Exhibit E - Environmental Report (18 CFR §5.18(b))

E.1 Introduction

Appalachian Power Company (Appalachian or Licensee) is the Licensee, owner, and operator of the two-development Byllesby-Buck Hydroelectric Project (Project) (Federal Energy Regulatory Commission [FERC or Commission] Project No. 2514), located on the upper New River in Carroll County, Virginia.

The Project is located approximately 60 miles south-southwest of the city of Roanoke. The Byllesby Development (Byllesby) is located about 9 miles north of the city of Galax, and the Buck Development (Buck) is located approximately 3 miles downstream of Byllesby and 43.5 miles upstream of Claytor Dam. Figure E.1-1 provides an overview of the Project setting and the FERC Project Boundary, and Figure E.2-1 shows the location of the Project within the New River watershed.

The Byllesby-Buck Project operates in a run-of-river mode under all flow conditions. Because the Buck Development is only 3 miles downstream from the Byllesby Development, operations of the two developments are closely coordinated and operations at Buck are dependent on flows through Byllesby. Under normal operating conditions, Appalachian operates the Project to use available flows for powerhouse generation, maintaining the elevation (EL.) of the Byllesby reservoir between 2,078.2 feet (ft) and 2,079.2 ft[1] and the Buck reservoir between 2,002.4 ft and 2,003.4 ft. Under the existing license, Appalachian is also required to release a minimum flow of 360 cubic ft per second (cfs) or inflow to the Project, whichever is less, downstream of the Project powerhouses.

The Project is currently licensed by the FERC under the authority granted to FERC by Congress through the Federal Power Act, 16 United States Code (USC) §791(a), et seq., to license and oversee the operation of non-federal hydroelectric projects on jurisdictional waters and/or federal land. The Project underwent relicensing in the early 1990s, and the current operating license for the Project expires on February 29, 2024. Accordingly, Appalachian is pursuing a new license for the Project pursuant to the Commission's Integrated Licensing Process (ILP), as described at 18 Code of Federal Regulations (CFR) Part 5. In accordance with FERC's regulations at 18 CFR §16.9(b), the licensee must file its final application for a new license with FERC no later than February 28, 2022.

[1] All elevations are referenced to the National Geodetic Vertical Datum of 1929 (NGVD)

E.1.1 Pre-Filing Consultation

Appalachian filed a Pre-Application Document (PAD) and associated Notice of Intent (NOI) with the Commission on January 7, 2019, to initiate the ILP. The Commission issued Scoping Document 1 (SD1) for the Project on March 8, 2019. As provided in 18 CFR §5.8(a) and §5.18(b), the Commission issued a notice of commencement of the relicensing proceeding concomitant with SD1. On April 10 and 11, 2019, the Commission held public scoping meetings and a site visit pursuant to 18 CFR §5.8(d). During these meetings, FERC staff presented information regarding the ILP and details regarding the study scoping process and how to request a relicensing study, including the Commission's study criteria. In addition, FERC staff solicited comments regarding the scope of issues and analyses for the Environmental Assessment. Resource agencies, Indian Tribes, NGOs, and other interested parties were afforded a 60-day period to request studies and provide comments on the PAD and SD1.

In accordance with ILP regulations, comments on the PAD and SD1 and study requests were due to FERC by May 7, 2019. Stakeholders filed letters with the Commission providing general comments, comments regarding the PAD and SD1, and/or study requests. Twenty-two formal study requests and/or comments were received during the comment period from the following stakeholders;

- Cherokee Nation
- Delaware Nation
- National Park Service
- New River Conservancy
- U.S. Fish and Wildlife Service (USFWS)
- Virginia Department of Conservation and Recreation (VDCR), Division of Planning and Recreation Resources and Division of Natural Heritage
- Virginia Department of Environmental Quality (VDEQ)
- Virginia Department of Wildlife Resources (VDWR) (formerly the Virginia Department of Game and Inland Fisheries [VDGIF])
- Virginia Department of Health (VDH)
- Virginia Polytechnic Institute and State University (Virginia Tech)

FERC issued Scoping Document 2 (SD2) on June 21, 2019, and, in accordance with 18 CFR §5.11, Appalachian developed a Proposed Study Plan (PSP) for the Project that was filed with the Commission and made available to stakeholders on June 21, 2019. The PSP described Appalachian's proposed approaches for conducting studies and addressed agency and stakeholder study requests. Pursuant to 18 CFR §5.11(e), Appalachian held a PSP Meeting on July 18, 2019, for the purpose of

clarifying the PSP, explaining initial information gathering needs, and addressing outstanding issues associated with the PSP. Appalachian received timely formal comments on the PSP from Commission staff, the USFWS, and VDGIF. Virginia Tech's College of Natural Resources and Environment filed multiple study requests on March 15, 2019.

In accordance with 18 CFR §5.11, Appalachian developed a Revised Study Plan (RSP) for the Project, which incorporated comments and study requests considered in developing the PSP, the Commission's June 21, 2019 SD2 and comments on the PSP, and it was filed with the Commission and made available to stakeholders on October 18, 2019. On November 18, 2019 FERC issued the Study Plan Determination (SPD). On December 18, 2019, Appalachian filed a request for rehearing of the SPD. The SPD was subsequently modified by FERC by an Order on Rehearing dated February 20, 2020. The modified SPD required eight studies to be performed in support of issuing a new license for the Project, as listed below:

1. Bypass Reach Flow and Aquatic Habitat Study
2. Water Quality Study
3. Aquatic Resources Study
4. Wetlands, Riparian, and Littoral Habitat Characterization Study
5. Terrestrial Resources Study
6. Shoreline Stability Assessment Study
7. Recreation Study
8. Cultural Resources Study

On July 27, 2020, Appalachian filed an updated ILP study schedule and a request for extension of time to file the Initial Study Report (ISR) to account for Project delays resulting from the COVID-19 pandemic. The request was approved by FERC on August 10, 2020, and the filing deadline for the ISR for the Project was extended from November 17, 2020 to January 18, 2021.

On December 23, 2020, FERC issued Scoping Document 3 (SD3) for the Project, to account for updates about how Commission staff intend to conduct their National Environmental Policy Act (NEPA) review in accordance with the Council on Environmental Quality's (CEQ) new NEPA regulations at 40 CFR Part 1500-1518.

Appalachian filed the ISR on January 18, 2021, conducted a virtual ISR Meeting on January 28, 2021, and filed the ISR Meeting summary with the Commission on February 12, 2021. Written comments in response to Appalachian's filing of the ISR meeting summary were filed by USFWS, VDWR, and FERC staff. Appalachian filed a response to comments on the ISR on April 13, 2021. Because no

substantive study modifications were requested in response to the ISR, FERC did not in turn provide a Determination on Requests for Study Modifications.

Appalachian is currently conducting the second year of studies and will submit an Updated Study Report (USR) on November 17, 2021.

Since July 2020, either by separate filing or in conjunction with the filings described above, Appalachian has provided FERC and relicensing participants with quarterly ILP study progress reports describing study activities completed by Appalachian, updates to the study schedule, and variances from the RSP due to field conditions or other developments.

In addition to the formal consultation activities describe above and as represented in Appendix A, Appalachian conducted consultation with specific stakeholders in support of the Cultural Resources Study, informal consultation with stakeholders in association with study activities, and also convened and participated in additional meetings with relicensing participants throughout the pre-filing consultation period, including:

- June 29, 2020: ILP Study Schedule Update to Agencies (Virtual Meeting) (VDWR, VDEQ, USFWS)
- August 28, 2020: Discussion of Byllesby-Buck Bypass Flow and Bypass Reach Study flow test scenarios (Virtual Meeting) (VDWR, USFWS, and VDEQ)
- October 23, 2020: Recreation Study Update (Virtual Meeting) (VDWR, VDCR-New River Trail State Park, USFWS, Carroll County, New River Conservancy)
- October 28, 2020: Byllesby-Buck Recreation Site Stakeholder Visit (VDWR, Carroll County, Land Planning Design Associates [LPDA], VDCR-New River Trail State Park)
- March 24, 2021: Recreation Stakeholder Meeting and Site Visit to Loafer's Rest recreational facility (VDWR)
- June 29, 2021: Potential Recreation Improvements Discussion with DWR (Virtual Meeting)

E.1.2 Resource Areas and Environmental Analysis Addressed in this Exhibit

As required by FERC's ILP regulations at 18 CFR § 5.18(b), this exhibit presents effects of the Project on environmental resources using the information filed in the Licensee's PAD, information developed through the Licensee's FERC-approved study plan, and other information developed or obtained by the Licensee. As a significant amount of information exists or has been developed for many resource areas, Appalachian has included here the most important and relevant information, and by reference

this Exhibit accounts for and reflects other relicensing filings, in particular the study reports that were filed with the ISR and that will be filed with the USR.

This environmental report contains information about the affected environment; analysis of anticipated continuing or new environmental impacts due to Project operation or proposed changes thereto, based on existing information and the results of relicensing studies (several of still are which ongoing as of the filing of this Draft License Application [DLA]); proposed environmental measures and measures recommended by relicensing participants; and unavoidable adverse impacts that may occur despite recommended or proposed environmental measures.

Consistent with the PAD and Scoping Documents 1, 2, and 3 issued by FERC, the following resources are addressed in this exhibit:

- Geology, geomorphology, and soils
- Water use and quality
- Fish and aquatic resources (including protected and sensitive species)
- Botanical, wetland, and terrestrial resources (including protected and sensitive species)
- Recreation, land use, and aesthetic resources
- Historic and archaeological resources
- Development resources

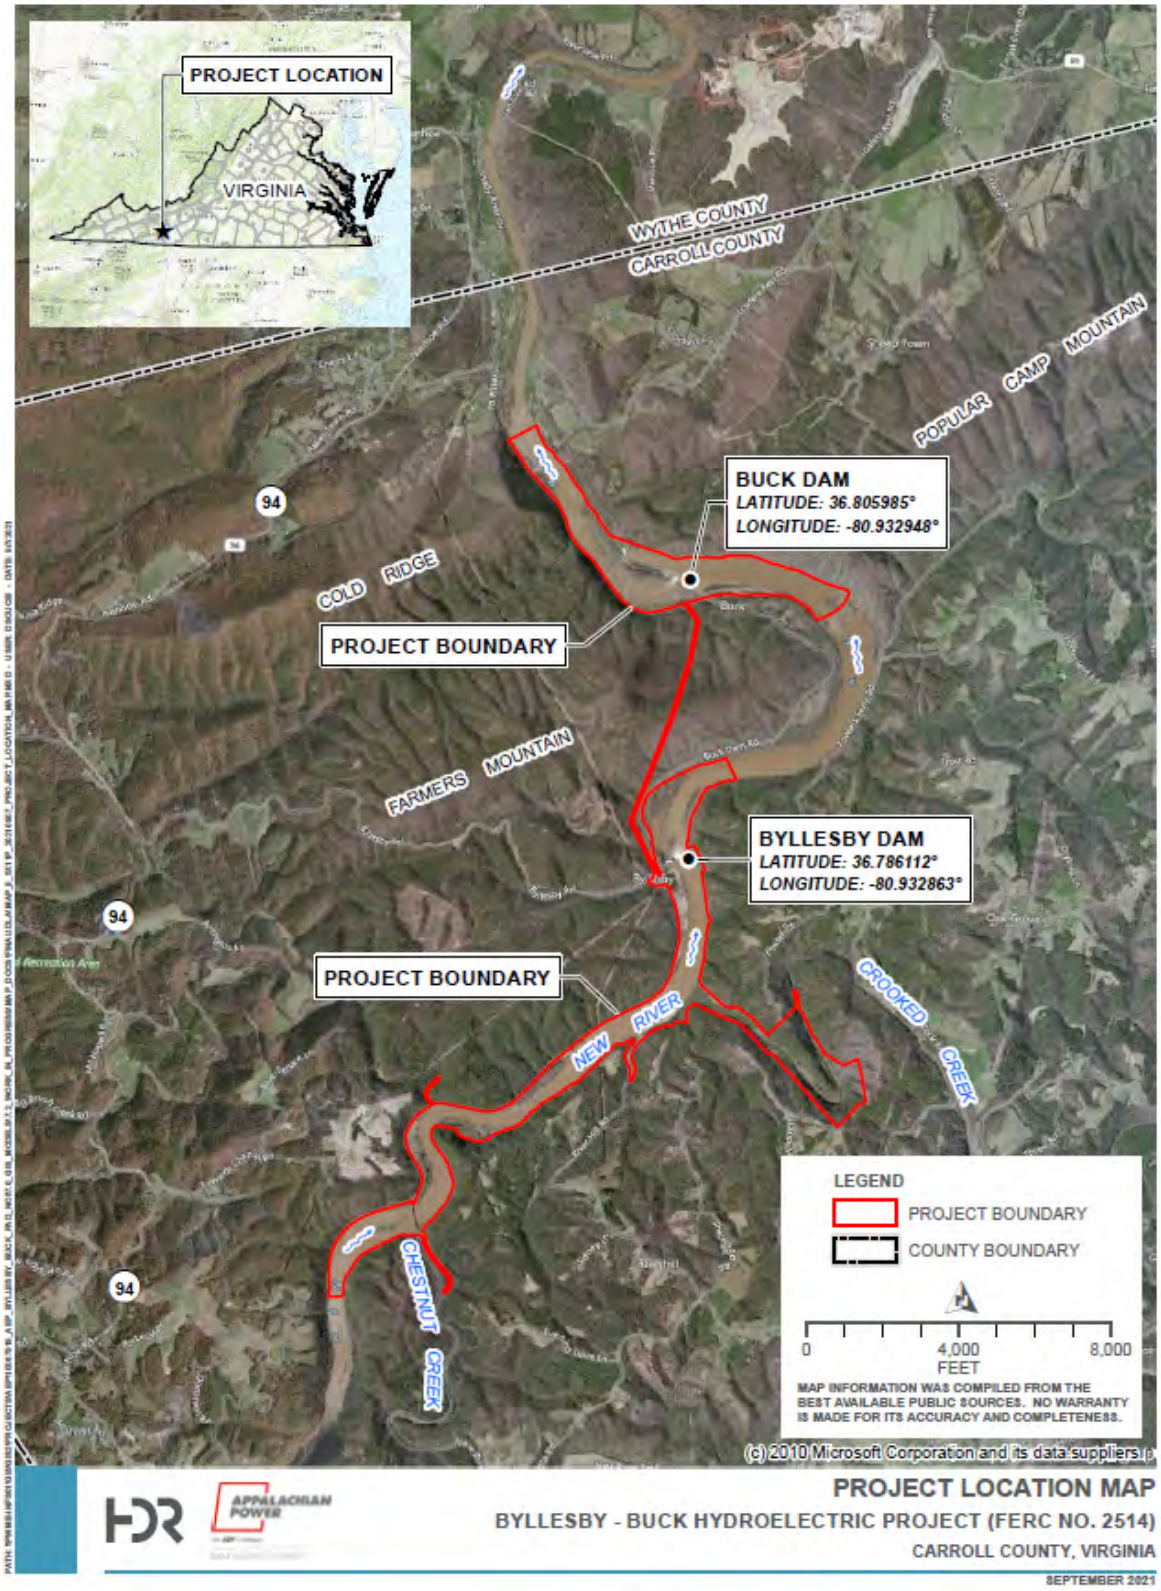

Figure E.1-1. Byllesby Buck Project Location Map

E.2 General Description of the River Basin

E.2.1 New River Watershed

The New River originates in North Carolina at the confluence of the North Fork New River and the South Fork New River. It then flows northward for 320 miles through Virginia before entering West Virginia and flowing to the confluence of the Gauley River forming the Kanawha River, a tributary to the Ohio River. The New River flows through valleys ranging in width from 200 to 1,000 ft and has banks with precipitous bluffs and steep side slopes. This terrain and the steep gradient of the river produce a fast runoff and high flow velocities.

The Byllesby and Buck developments are within the upper New River Basin (Hydrologic Unit Code 050500) which extends from the Bluestone Dam near Hinton, West Virginia, to the headwaters of the New River's north and south forks in northwestern North Carolina near Blowing Rock. The drainage area for the Byllesby Development is 1,310 square miles and 1,320 square miles for the Buck Development.

E.2.2 Geography, Topography, and Climate

The Project is located within the Southern Blue Ridge Physiographic Province on the Blue Ridge Plateau, an upland area with numerous knobs and ridges ranging in elevation from about 2,000 to 3,000 ft. The Blue Ridge Escarpment, a southwest to northeast-trending range of mountains, separates the Blue Ridge Plateau from the Piedmont lowlands to the southeast (Appalachian 1991a). The northwestern border of the Blue Ridge Plateau is formed by the southwest to northeast- trending Iron and Poplar Camp Mountains, beyond which lies a portion of the Great Valley, an extension of the Appalachian Valley, an area known as the Valley and Ridge Physiographic Province. The topography of the New River Basin and the Project area, is rugged, consisting of high mountains, narrow valleys, and steep ravines. The valley in which the Project is situated ranges from 700 to 1,000 ft in width and the adjacent slopes are steep with exposed bedrock.

In Carroll County, the average low temperature is 28ºF (January) and the average high temperature (August) is 87ºF. Average annual total rainfall is 58.7 inches with approximately 15 snow days per year based on historical data from the last ten years (Carroll County 2021).

E.2.3 Dams and Diversions in the Watershed

There are a total of seven dams on the New River (Table E.2-1 and Figure E.2-1). The non-FERC jurisdictional Fields Dam and the FERC jurisdictional Fries Dam are the only major dams located upstream of the Byllesby-Buck Project. There are three major dams located on the New River downstre

am of the Project, which are the Claytor (also owned and operated by Appalachian), Bluestone, and Hawks Nest dams.

Table E.2-1. Dams and Diversion Structures on the New River

Development/ Dam	Owner	River Mile	FERC Project No.	Expiration of Current License	Capacity (MW)
Fields	Fields Electric	323	N/A	N/A	Unknown
Fries	Aquenergy Systems	303.6	P-2883	2020	5.2
Byllesby	Appalachian Power Company	295	P-2514	2024	21.6
Buck	Appalachian Power Company	292.3	P-2514	2024	8.5
Claytor	Appalachian Power Company	248.8	P-739	2041	75
Bluestone	U.S. Army Corps of Engineers (USACE)	162.4	N/A	N/A	N/A
Hawks Nest	Hawks Nest Hydro	103.57	P-2512	2064	102

Figure E.2-1. Kanawha River Basin and Location of Project

E.2.4 Tributary Rivers and Streams

The major tributaries in the New River Basin include Indian Creek, the Bluestone River, and the Greenbrier River. Tributaries to the New River near the Byllesby-Buck Project include Big Branch, Poor Branch, and a couple of unnamed tributaries. The Project boundary of the Byllesby Development extends upstream into the lower reach of Crooked Creek, Brush Creek, and Chestnut Creek (see Figure E.2-1).

E.2.5 General Land and Water Use

The New River basin is the least densely populated of Virginia's major river basins. The higher elevations of the New River basin are steep sloped and primarily forested (59 percent), while the lowlands are mostly (35 percent) pasture and cropland (VDEQ 2015). Land use within the Project area consists primarily of deciduous forest with small amounts of evergreen forest, pasture/hay fields, and other land cover. Table E.2-2 lists the estimated land use acreage within the Project Boundary and land use types are also shown on Figure E.2-1. The forest cover is of the oak-chestnut type with a noteworthy percentage of pine and other types such as hickory, hemlock, maple, ash, birch, rhododendron, locust and basswood (Appalachian 1991a).

Table E.2-2. Estimated Land Use Coverage (Acres) within the Project Boundary

Land Use	Estimated Acres
Barren Land	1.11
Deciduous Forest	197.34
Developed, Low Intensity	1.89
Developed, Open Space	7.46
Emergent Herbaceous Wetlands	12.37
Evergreen Forest	33.53
Hay/Pasture	11.41
Herbaceous	13.60
Mixed Forest	22.19
Open Water	369.05
Shrub/Scrub	14.25
Woody Wetlands	23.24
Grand Total	**707.44**

Data Source: National Land Cover Database 2011

Most of the land to the west of the Project is owned by the U.S. Forest Service (USFS) and consists of the George Washington and Jefferson National Forest. The Mount Rogers National Recreation Area, a unit within the Jefferson National Forest and created in 1966, borders the Project to the west, as illustrated by the light green shading in Figure E.2-2. These lands include approximately 100 acres of former Project lands that were transferred by Appalachian to the U.S. Forest Service in 1984, and subsequently removed from the Project boundary, as authorized by FERC order dated December 18, 1984. There are currently no federal lands within the Project boundary.

E.2.6 Downstream Reach Gradients

The river has an average gradient of approximately 6.3 ft/mile through the upper New River Basin (Appalachian 1991a), compared to an average gradient of 20 ft/mile one mile downstream of the Project and of approximately 24 ft/mile in the Buck bypass reach. The gradient of the Byllesby bypass reach is known to be steep as well, though detailed digital elevation model data is not available to calculate the gradient over this short (approximately 475 ft) reach.

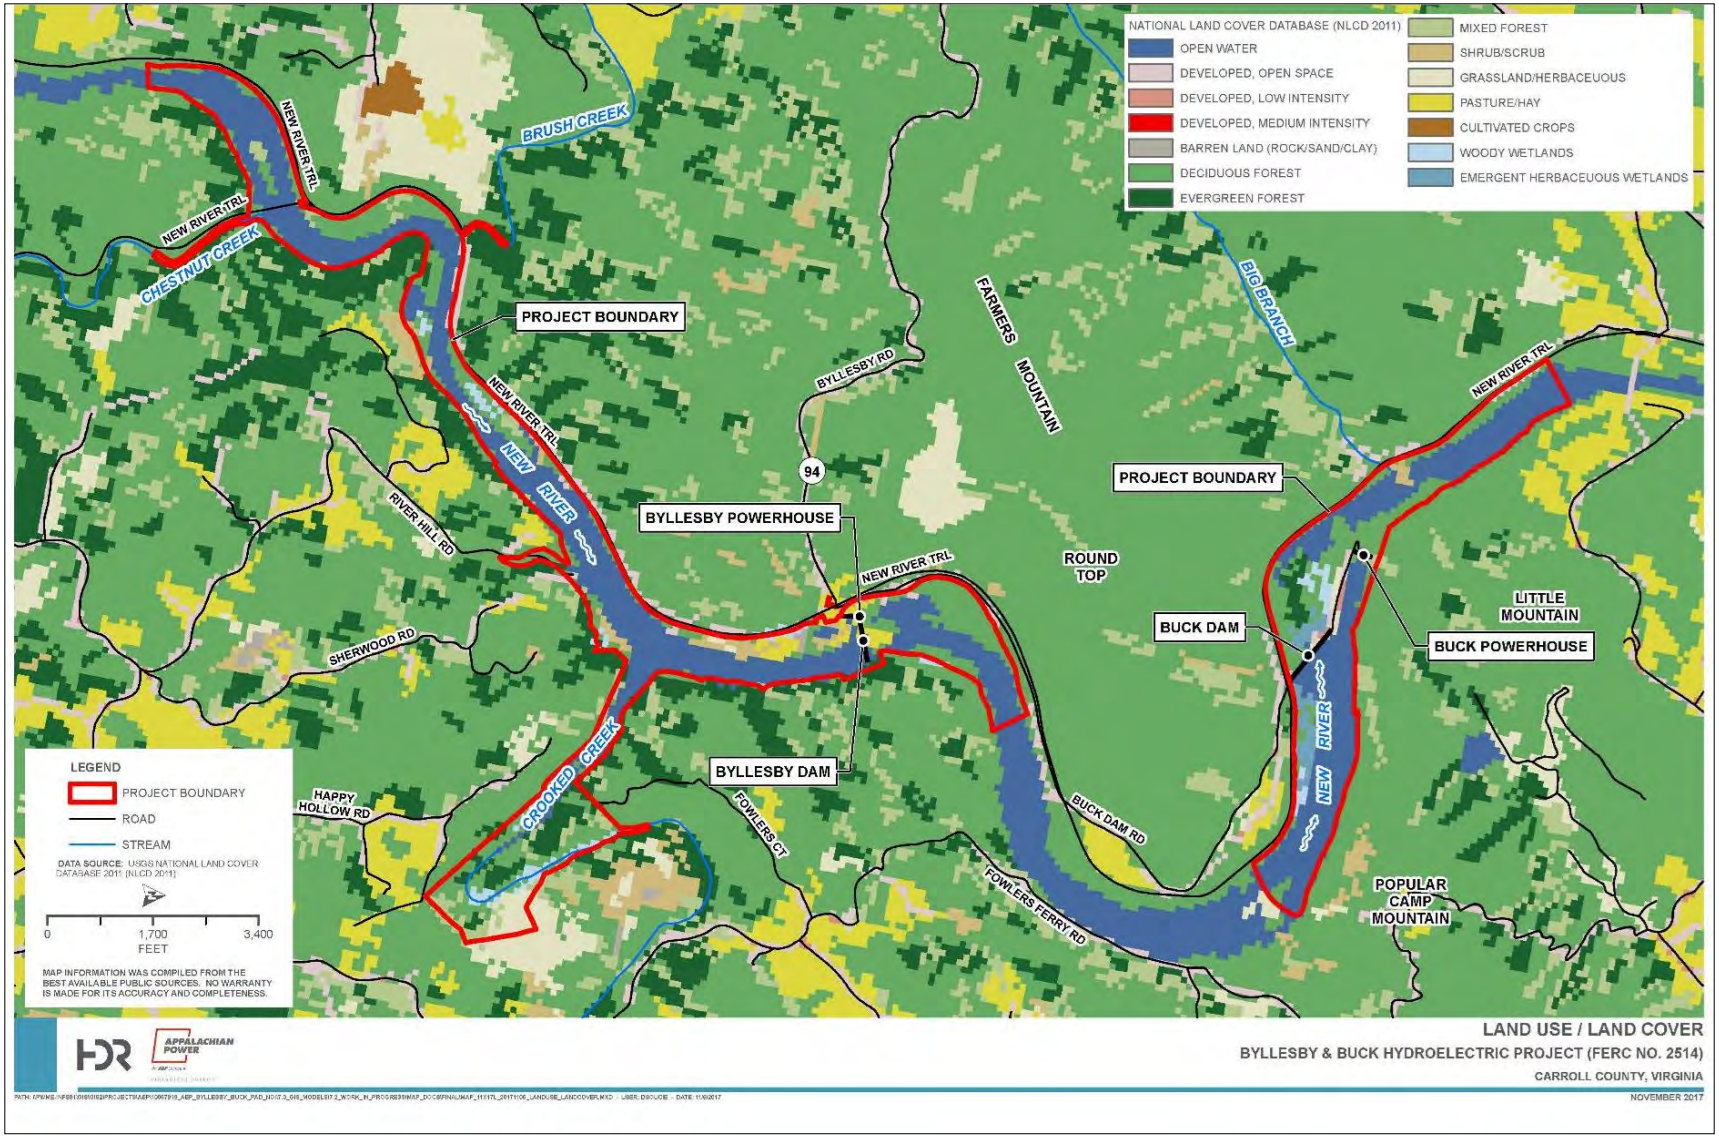

Figure E.2-1. Land Use and Land Cover

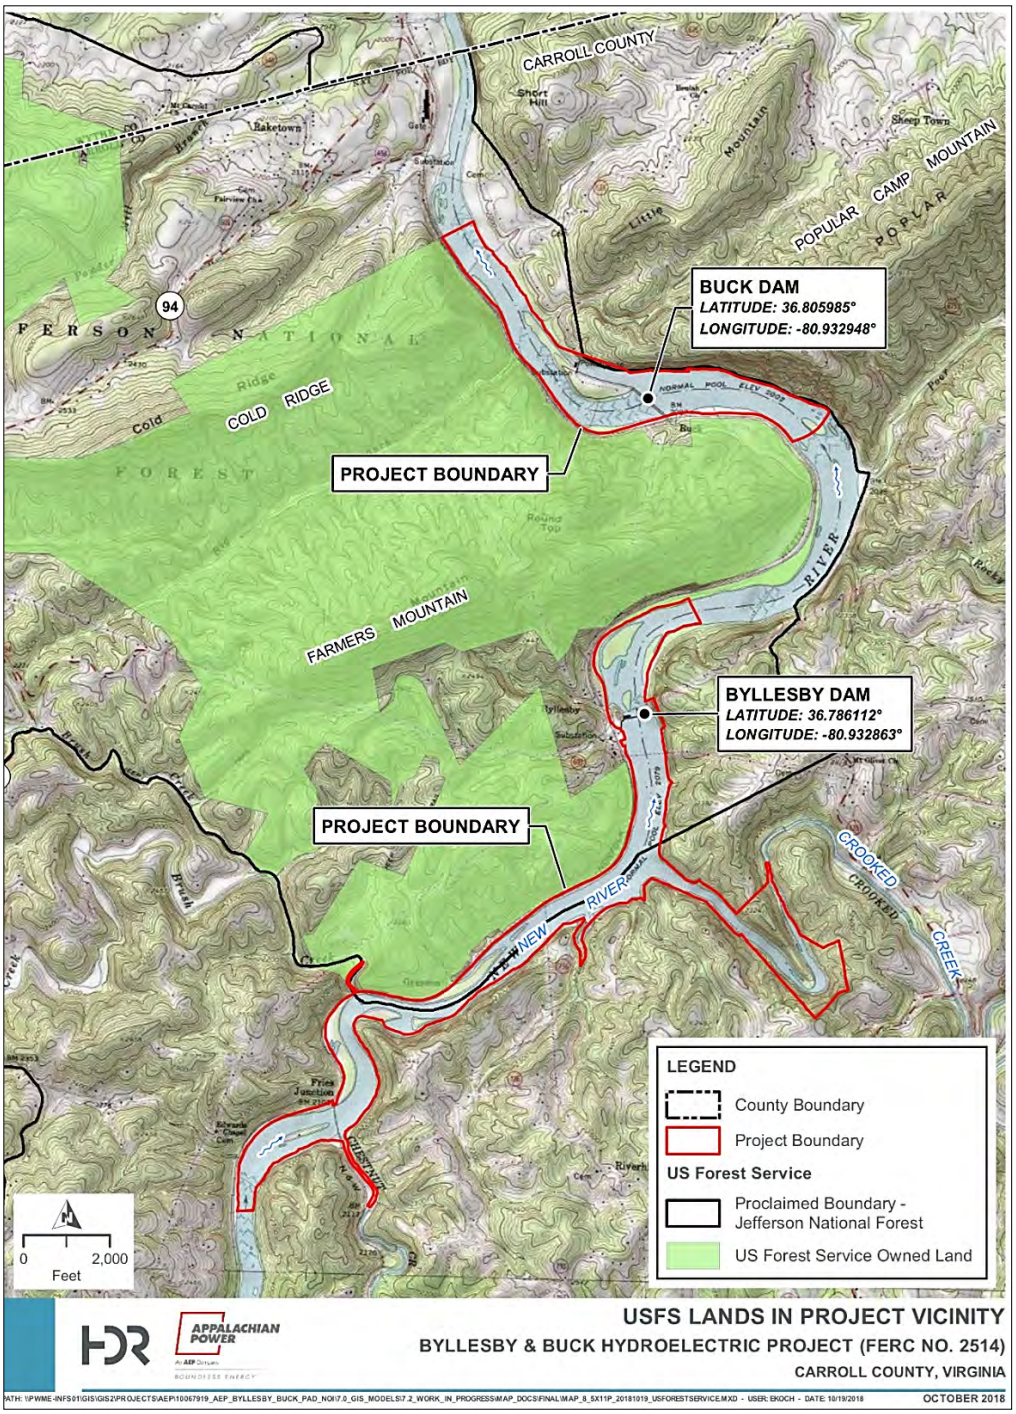

Figure E.2-2. USFS Lands in Project Vicinity[2]

[2] Not all lands within the proclamation boundary of a national Forest are owned by the U.S. Forest Service. Privately held lands within a proclamation boundary, including land interest held prior to the creation of the national Forest and not taken in condemnation proceedings, are termed inholdings" and are not subject to provisions of the Federal Power Act for licensing projects on federal lands (see 54 FERC ¶61, 132[1991])

E.3 Cumulative Effects

According to the CEQ regulations for implementing NEPA (40 CFR § 1508.7), a cumulative effect was historically defined as the effect on the environment that results from the incremental effect of the action when added to other past, present, and reasonably foreseeable future actions, regardless of what agency (federal or non-federal) or person undertakes such other actions. Cumulative effects can result from individually minor but collectively significant actions taking place over a period of time, including hydropower and other land and water development activities.

However, in a final rule issued on July 15, 2020, CEQ revised its regulations under 40 CFR Parts 1500-1518 that federal agencies use to implement NEPA. The revised regulations repealed the definition of cumulative effects and provided a new definition for effects to be considered in the environmental analysis as follows; FERC's NEPA document will be consistent with this definition:

> *Effects or impacts means changes to the human environment from the proposed action or alternatives that are reasonably foreseeable and have a reasonably close causal relationship to the proposed action or alternatives, including those effects that occur at the same time and place as the proposed action or alternatives and may include effects that are later in time or farther removed in distance from the proposed action or alternatives.*
>
> *(1) Effects include ecological (such as the effects on natural resources and on the components, structures, and functioning of affected ecosystems), aesthetic, historic, cultural, economic (such as the effects on employment), social, or health effects. Effects may also include those resulting from actions that may have both beneficial and detrimental effects, even if on balance the agency believes that the effect will be beneficial.*
>
> *(2) A ''but for'' causal relationship is insufficient to make an agency responsible for a particular effect under NEPA. Effects should generally not be considered if they are remote in time, geographically remote, or the product of a lengthy causal chain. Effects do not include those effects that the agency has no ability to prevent due to its limited statutory authority or would occur regardless of the proposed action.*

On the basis of this regulatory change, and because FERC did not identify any resources that could be cumulatively affected by the proposed continued operation and maintenance of the Project in their scoping documents, Appalachian is not separately addressing cumulative effects in this DLA.

E.4 Compliance with Applicable Laws

E.4.1 Section 401 of the Clean Water Act

Under Section 401 of the Clean Water Act (CWA) (33 USC § 1251 et seq.), a federal agency may not issue a license or permit to conduct any activity that may result in any discharge into waters of the United States unless the state or authorized tribe where the discharge would originate either issues a Section 401 Water Quality Certification finding compliance with existing water quality requirements or waives the certification requirement. In the Commonwealth of Virginia, under § 62.1-44.15 of the Code of Virginia, the VDEQ provides Section 401 Water Quality Certification through the Virginia Water Protection (VWP) Program, as authorized by the State Water Control Law and as described in the VWP Permit Regulation.

Appalachian is preparing a joint permit application for a VWP permit and surface water withdrawal for the continued operation of the Project in parallel with the FERC licensing process and intends, to the greatest extent possible, to use licensing documents including but not limited to study reports and the license application exhibits to satisfy this parallel regulatory process. Requirements for a VWP permit are described in 9 Virginia Administrative Code (VAC) 25-210-80 and 9VAC25-210-340. Pursuant to 18 CFR § 5.23(b), Appalachian will file an application for water quality certification with VDEQ no later than 60 days of the Commission's Notice of Acceptance and Ready for Environmental Analysis. The VDEQ must act on the request for WQC within the one-year timeframe allowed under the CWA.

E.4.2 Endangered Species Act

Section 7 of the Endangered Species Act (ESA) (19 USC §1536(c)), as amended, requires federal agencies to ensure that their actions are not likely to jeopardize the continued existence of endangered or threatened species or result in the destruction or adverse modification of the critical habitat of such species. Under the ESA, the USFWS is responsible for freshwater and terrestrial species, and the National Marine Fisheries Service (NMFS) (National Oceanic and Atmospheric Administration [NOAA] Fisheries) is responsible for marine and anadromous species (not applicable to the Byllesby-Buck Project). In the notice of the Licensee's intent to file a Final License Application (FLA), filing of the PAD, commencement of pre-filing process, and scoping issued on March 26, 2019, the Commission designated Appalachian as the Commission's non-federal representative for carrying out informal consultation pursuant to Section 7 of the ESA. Information from the USFWS and the VDWR and collected during execution of the relicensing studies has been used by the Licensee to identify endangered or threatened species in the Project area. A discussion of the rare, threatened, and endangered (RTE) species relevant to the Project is contained in Sections E.9.1.5 and E.11.

E.4.3 Magnuson-Stevens Fishery Conservation and Management Act

The 1996 amendments to the Magnuson-Stevens Act authorized the NMFS, in accordance with regional fisheries management councils, to delineate essential fish habitat (EFH) for the protection of habitat of marine, estuarine, and anadromous finfish, mollusks, and crustaceans. Essential Fish Habitat includes "those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity." The Project area is not located within designated EFH for any species.

E.4.4 Coastal Zone Management Act

Section 307(c)(3) of the Coastal Zone Management Act requires that activities conducted or supported by a federal agency that affect the coastal zone be consistent with the enforceable policies of the federally-approved state coastal management plan to the maximum extent practicable. Policies associated with the Coastal Zone Management Act are not applicable to the Project, which is not located within Virginia's designated Coastal Zone. By letter dated September 1, 2017, VDEQ's Office of Environmental Impact Review confirmed that Carroll County is not located within Virginia's coastal management area and that it appeared to be unlikely that the Project would affect any land or water use or natural resources of Virginia's designated coastal resources management plans; therefore, a federal consistency certification is not required for this relicensing.

E.4.5 National Historic Preservation Act

Section 106 of the National Historic Preservation Act of 1966 (NHPA) (54 USC §300101 et seq.) requires federal agencies to take into account the effects of their undertakings on historic properties and to afford the Advisory Council on Historic Preservation a reasonable opportunity to comment on such actions. Historic properties include significant sites, buildings, structures, districts, and individual objects listed in or eligible for inclusion in the National Register of Historic Places (NRHP). If a property has not yet been nominated to the NRHP for determined eligible for inclusion, it is the responsibility of FERC to ascertain its eligibility.

The Commission's issuance of a new license for the continued operation of the Project is considered an undertaking subject to the requirements of Section 106 and its implementing regulations. FERC initiated consultation under Section 106 with federally recognized Indian tribes by letter dated April 25, 2018. By notice dated March 8, 2019, FERC designated Appalachian as its non-federal representative for purposes of conducting informal consultation pursuant to Section 106.

E.4.6 Wild and Scenic Rivers and Wilderness Act

The reach of the New River in the vicinity of the Project is not located within or adjacent to any presently designated National Wild and Scenic River systems or state protected river segments. The Project does not occur in or occupy lands designated as wilderness area under the Wilderness Act.

E.5 Project Facilities and Operations

E.5.1 Maps of Project Facilities Within Project Boundary

The following figures in this DLA depict the Project facilities within the Project Boundary:

- Exhibit G – Project Boundary Map (Volume III)
- Figure E.1-1 – Project Location Map with Project Boundary
- Figure A.2-1 and A.2-2 of Volume I, Exhibit A – Existing Project Facilities

E.5.2 Project Facilities

The Byllesby Development consists of (1) a 64-ft-high, 528-ft-long concrete dam, sluice gate, and main spillway section topped with four sections of 9-ft-high flashboards, five sections of 9-ft-high inflatable Obermeyer crest gates, and six bays of 10-ft-high Tainter gates; (2) an auxiliary spillway including six sections of 9-ft-high flashboards; (3) a 239-acre reservoir with a gross storage capacity of approximately 2,000 acre-ft; (4) a powerhouse containing four generating units with a total installed capacity of 21.6 MW; (5) a control house and switchyard; and (6) appurtenant facilities.

The Buck Development consists of (1) a 42-ft-high, 353-ft-long concrete dam and sluice gate; (2) a 1,005-ft-long, 19-ft-high spillway section topped with 20 sections of 9-ft-high flashboards, four sections of 9-ft-high inflatable Obermeyer crest gates, and six bays of 10-ft-high Tainter gates; (3) a 66-acre impoundment with a gross storage capacity of approximately 661 acre-ft; (4) a powerhouse containing three generating units with a total installed capacity of 8.5 MW; (5) a two 2-mile long overhead 13.2-kV transmission lines extending from the Buck powerhouse to the Byllesby control house; and (6) appurtenant facilities.

E.5.3 Project Waters

Both developments have little storage capacity or ability to regulate river flow; inflow is either used for generation or passed through the spillway. The reservoir formed by the Byllesby Dam is approximately 16.8 miles long with a surface area of 239 acres at EL. 2,079.2. The Byllesby Development includes a short, 475-ft-long bypass reach consisting primarily of exposed bedrock and rock outcroppings.

The reservoir formed by the Buck Dam is approximately 5.8 miles long with a surface area of 66 acres at EL. 2,003.4 ft. The Buck Development includes a 4,100-ft-long, steep bypass reach consisting of exposed bedrock.

Flow from the Project is measured at the U.S. Geological Survey (USGS) 03165500 New River at Ivanhoe, VA gauge, which is located approximately 2.8 miles downstream of the Buck Development

E.5.4 Turbine and Generator Specifications

Existing turbine and generator specifications for both developments are included in Volume I (Exhibit A) of this DLA and are also provided in the tables below for reference.

Table E.5-1. Byllesby Turbine and Generator Data – Existing

Turbines	
Number of Units	4
Type	Vertical Francis, I.P. Morris Co.
Design Head	49 ft
Rated Capacity	6,000 hp / 4,500 kW (each unit)
Minimum Discharge	73 cfs (per unit)
Maximum Discharge	1,467 cfs (per unit)
Operating Speed	116 rpm
Generators	
Type	Vertical configuration, General Electric Co.
Rated Capacity	5,400 kW (per unit)
Power Factor	0.9
Phase	3 PH (per unit)
Voltage	13,200 V (per unit)
Frequency	60 Hz (per unit)
Synchronous Speed	116 rpm (per unit)

Table E.5-2. Buck Turbine and Generator Data – Existing

Turbines	
Number of Units	3
Type	**Units 1 and 3:** Vertical Francis, I.P. Morris Co. **Unit 2:** American Hydro
Design Head	34 ft
Rated Capacity	**Units 1 and 3**: 3,500 hp / 2,626 kW **Unit 2:** 4,480 hp / 3,360 kW
Minimum Discharge	60 cfs (per unit)
Maximum Discharge	1,180 cfs (per unit)
Operating Speed	97 rpm
Generators	
Type	Vertical configuration, General Electric Co.
Rated Capacity	2,835 kW (per unit)
Power Factor	0.9
Phase	3 PH (per unit)
Voltage	13,200 V (per unit)
Frequency	60 Hz (per unit)
Synchronous Speed	97 rpm (per unit)

E.5.5 Dependable Capacity and Average Annual Energy Production

The Project has been operated by Appalachian over the previous license term in a run-of-river mode, utilizing upper New River inflows to provide up to 30.1 MW of renewable capacity and average annual energy generation of 92,891 megawatt hours (MWh) based on recent generation data.

The Project operates to provide dependable winter and summer season capacities (combined for both developments) of 13 MW and 8 MW, respectively. These estimates are based on the monthly project flow duration curves for the months of January (winter season) and August (summer season) and manufacturer's data relative to equipment performance.

E.5.6 Project Operations

The Byllesby-Buck Project operates in a run-of-river mode under all flow conditions. Because the Buck Development is approximately 3 miles downstream from the Byllesby Development, operations of the two developments are closely coordinated and operations at Buck are dependent on flows through Byllesby. Under normal operating conditions, Appalachian operates the Project to use available flows for powerhouse generation, maintaining the elevation of the Byllesby reservoir between 2,078.2 ft and 2,079.2 ft and the Buck reservoir between 2,002.4 ft and 2,003.4 ft. Appalachian is also required to

release a minimum flow of 360 cfs or inflow to the Project, whichever is less, downstream of the Project powerhouses.

Under normal operating conditions, the minimum flow requirements and normal headwater elevation is maintained by passing flow through the turbine generating units. The unit operations are monitored and controlled either locally from the plant's computer or remotely from AEP's COC in Columbus, Ohio. Tainter gate and Obermeyer gate operation at both Byllesby and Buck are also remotely controlled from AEP's COC. Operators are stationed at the control center twenty-four hours per day, seven days per week. Plant personnel are typically present at the Project during normal working hours Monday through Thursday to perform routine maintenance. The plant is staffed four days a week (typically Monday through Thursday), 10 hours a day during normal operating conditions.

As further described in Exhibit B, when inflow to either development exceeds the discharge capacity of the powerhouse (5,868 cfs for Byllesby and 3,540 cfs for Buck), the Tainter gates and/or Obermeyer gates are opened to pass the excess flow. The Byllesby auxiliary spillway has historically been operated after all Tainter and Obermeyer gates have been opened and release of all wooden flashboard sections, typically at flows in excess of 46,690 cfs. Gate openings are planned and based on monitoring of the U.S. Geological Survey (USGS) gage at Galax, VA and Byllesby and Buck forebay elevations. If inflows exceed the capacity of the Tainter and Obermeyer gates, the wooden flashboards are manually released. The wooden flashboards must then be subsequently re-installed during a period when the reservoir is drawn down to the spillway crest elevation.

Ramping rates are required under Article 406 of the license for the protection of fish resources downstream of the Buck spillway. The gradual reduction of flow allows fish to progressively leave the area, versus possible stranding at sudden flow discontinuation. Following periods of spill from the Buck spillway when a spillway gate has been opened 2 ft or more, Appalachian is required to discharge flows through a 2-ft gate opening for at least three hours. Appalachian is then required to reduce the opening to 1 ft for at least an additional 3 hours, after which Appalachian may close the gate.

E.6 Proposed Action and Alternatives

E.6.1 No-Action Alternative

Under the no-action alternative, the Project would continue to operate as required by the current license (i.e., there would be no change to the existing environment). No new environmental protection, mitigation, and enhancement (PM&E) measures would be implemented. This alternative establishes baseline environmental conditions for comparison with other alternatives.

The following resource protection measures are required by the existing license and implemented by Appalachian:

- Geological and Soil Resources
    - There are no specific license article requirements related to geology and soils for the Project; however, bank erosion is monitored annually by Appalachian in consultation with VDWR through implementation of the Wildlife Management Plan required by Article 408. Operation of the Project in a run-of-river mode with maintenance of the reservoirs within a narrow operating band provides relatively stable water levels in the reservoirs that serve to reduce the potential for shoreline erosion due to Project operation.
- Aquatic Resources
    - Operate the project in a run-of-river mode, maintaining the Byllesby reservoir between EL. 2,078.2 ft and 2,079.2 ft and the Buck reservoir between EL. 2,002.4 ft and 2,003.4 ft (Article 401).
    - Provide a minimum flow of 360 cfs, or inflow to the project, whichever is less, to the New River downstream of the powerhouse (Article 403).
    - Implement the existing ramping rate for the Buck bypassed reach; whereby, following periods of spill when a spillway gate has been opened 2 ft or more, water will continue to be released into the bypassed reach through a 2-ft-gate opening for at least 3 hours, then the gate opening will be reduced to 1.0 ft for 3 hours before closing the gate (Article 406).
- Terrestrial Resources
    - Continue to follow the Commission-approved Wildlife Management Plan that includes provisions to annually inspect undeveloped land within the project boundary for evidence of increased human disturbance, consult with VDWR about activities that affect these lands and notify VDWR of any unanticipated impacts within these lands, and monitor bank erosion (Article 408).

- Threatened and Endangered Species
    - There are no existing license article requirements related to threatened and endangered species for the Byllesby-Buck Project. However, due to the potential for protected species to occur in Project waters as later described in this document, Appalachian has performed, in consultation with natural resource agencies, species-specific surveys and mussel salvage efforts in support of recent reservoir drawdowns and other activities in support of Project maintenance activities.

- Recreation and Land Use and Aesthetic Resources
    - Continue to follow a Commission-approved Recreation Plan and continue to provide Project recreation access, monitor recreation use and demand, consult with interested stakeholders on potential recreation enhancement measures, and update the Recreation Plan as needed (Article 411).
- Cultural Resources
    - Continue to follow a Commission-approved Cultural Resources Management Plan (CRMP) (Article 409).

E.6.2 Applicant's Proposal

The proposed action is to continue the existing operation and maintenance of the Project, with additional PM&E measures that will be proposed in the FLA. Additionally, during the new license term, Appalachian proposes to modernize the Byllesby and Buck developments to include replacement of Byllesby Units 1, 2, and 4 and Buck Units 1 and 3. All but one (Buck Unit 2) of the seven turbine-generator units installed at the Project are the original major components of the Project as constructed in 1912. Many of the major electrical and mechanical and supporting systems and components of the Project are nearing the end of their useful service life, when compared to industry-recognized standards. Appalachian is presently planning a three-phase unit replacement program for the Project. The first phase involves the replacement of Byllesby Unit 4 starting in 2024. The second phase involves the replacement of Byllesby Units 1 and 2 in 2025 and 2026; existing Byllesby Unit 3 would remain in place and would be operated as last unit on and first unit off. The third phase involves the replacement of Buck Units 1 and 3 in 2027 and 2028, respectively. Existing Buck Unit 2 would remain in place and would be operated as last unit on and first unit off.

The existing vertical Francis units would be replaced by fixed blade Kaplan units. Unit upgrade activities would be confined to within the powerhouse, and there would be minimal changes to operating parameters for the Project. Following completion of the upgrades, the authorized installed capacities for the Byllesby and Buck developments will be 20.85 MW and 10.39 MW, respectively, with maximum hydraulic capacities of 5,511 cfs and 3,570 cfs, respectively. Due to efficiencies of the Kaplan units and modern components, the upgrades are expected to increase average annual

generation at the Project by approximately 25,927 MWh. Specifications for the upgraded turbine-generator units are provided in Volume I (Exhibit A) of this DLA. Upgraded turbine and generator specifications are included in Volume I (Exhibit A) of this DLA and are also provided in the tables below for reference.

Because relicensing studies and associated stakeholder consultation activities are ongoing, Appalachian is still evaluating measures, including PM&E measures and other potential Project modifications, to be included in Appalachian's licensing proposal. This section will be updated in the FLA.

Table E.6-1. Byllesby Development Turbine and Generator Data – Proposed (Upgrades to Units 1, 2, and 4)

Turbines	
Number of Units	4
Type	**Units 1, 2, and 4:** Vertical Kaplan, Mavel **Unit 3:** Vertical Francis, I.P. Morris Co.
Design Head	**Units 1, 2, and 4:** 54 ft **Unit 3:** 49 ft
Rated Capacity	**Units 1, 2, and 4:** 7,544 hp / 5,658 kW (per unit) **Unit 3:** 6,000 hp / 4,500 kW
Maximum Discharge	**Units 1, 2, and 4:** 1,348 cfs (per unit) **Unit 3:** 1,467 cfs
Operating Speed	**Units 1, 2, and 4:** 189.47 rpm **Unit 3:** 116 rpm
Generators	
Type	**Units 1, 2, and 4:** Vertical configuration, Mavel **Unit 3:** Vertical configuration, General Electric Co.
Rated Capacity	**Units 1, 2, and 4:** 5,885 kVA / 5,296.5 kW (per unit) **Unit 3:** 5,400 kW (per unit)
Power Factor	0.9
Phase	3 PH (per unit)
Voltage	13,200 V (per unit)
Frequency	60 Hz (per unit)
Synchronous Speed	**Units 1, 2, and 4:** 189.47 rpm (per unit) **Unit 3:** 116 rpm

Maximum Discharge	**Units 1 and 3:** 1,195 cfs (per unit) **Unit 2:** 1,180 cfs
Operating Speed	**Units 1 and 3:** 156.52 rpm **Unit 2:** 97 rpm
Generators	
Type	**Units 1 and 3:** Vertical configuration, Mavel **Unit 2:** Vertical configuration, General Electric Co.
Rated Capacity	**Units 1 and 3:** 4,100 kVA / 3,690 kW (per unit) **Unit 2:** 2,835 kW
Power Factor	0.9

Phase	3 PH (per unit)
Voltage	13,200 V (per unit)
Frequency	60 Hz (per unit)
Synchronous Speed	**Units 1 and 3:** 156.52 rpm **Unit 2:** 97 rpm

E.6.3 Alternatives

For the reasons described in FERC's SD3, Federal Government Takeover, issuance of a non-power license, and Project decommissioning are not considered to be reasonable alternatives based on the relicensing proceeding to date and are not expected to be analyzed in FERC's NEPA document.

E.7 Geology, Geomorphology, and Soils

E.7.1 Affected Environment

E.7.1.1 Geology

E.7.1.1.1 Regional Geology

The Blue Ridge Plateau begins narrowly just south of Roanoke, Virginia, and widens to nearly 50 miles, with Mount Rogers rising from the base. The Blue Ridge Plateau is a maturely dissected plain with rugged topography formed by numerous stream valleys that are 300 to 400 ft deep. The geologic structures comprising the region extend from the Roanoke, Virginia, area southwestward into Tennessee. The bedrock in this region has undergone folding and faulting (e.g., thrust faulting), which is apparent in cross-section. Thrust faults are shallow-dipping planar fractures which form in response to horizontal compressive stresses and oftentimes result in older rocks being placed on top of younger rocks. Lateral compression from the southeast formed these faults (as well as the northwestward displacements associated with them) during a mountain-building episode, or orogeny, during the late Paleozoic era (~200-245 million years ago). The original rocks from which these structures formed are of Precambrian and Cambrian age, and include igneous extrusive and intrusive rocks, sedimentary rocks, and several grades of derived metamorphic rocks. Overall, the regional geology of the Project area is quite complex, in part because the intense folding and southwest- to-northeast striking thrust faults have disrupted the original stratigraphic age relationships (Appalachian 1991a).

The effects of the late Paleozoic orogeny and subsequent erosion have resulted in the formation of parallel outcrops of rock ranging from less than one-tenth of a mile to several miles wide and extending many tens of miles trending in a southwest to northeast direction. The ages and geologic origins of adjacent rock units vary greatly and are often difficult to interpret due to overthrusting. Resistant rocks have formed ridges (i.e., sandstone and conglomerate) while less resistant rocks (i.e., limestone and shale) underlie valleys (Appalachian 1991a).

E.7.1.1.2 Local Geology

Although the Byllesby and Buck developments are within 1.2 miles of each other, they overlie different rock formations, both of Lower Cambrian age. The Byllesby Development is founded on a locally mapped arkosic unit of the middle member of the Unicoi Formation, and the Buck Development overlies the Erwin Quartzite, a slightly younger formation. These distinctions are explained below (Appalachian 1991a).

The Unicoi Formation occurs in a thin band about one mile wide, trending southwest to northeast between the Fries Overthrust to the southeast and the Byllesby Overthrust to the northwest. Approximately five miles southwest of the Byllesby Development, the Unicoi Formation bifurcates into westward and southwestward trending branches as it traces around the plunging Elk Creek Anticline. The Byllesby Development lies about 300 ft south of the Byllesby Overthrust. The Unicoi Formation contains arkosic, or feldspar-rich quartzite, shale, argillite, beds of conglomerate, and basalt flows. The middle member of this formation comprises the bedrock in the vicinity of the dam. Basalt flows with black argillite are present about 600 ft upstream of the dam, and a similar, locally mapped unit also containing arkose is found beneath the dam and on both abutments. The dam and its appurtenances are founded on bedrock because of very thin or absent soil cover in the area. The basalt is resistant to erosion and forms cliffs along the right side of the New River about one mile downstream of the dam (Appalachian 1991a).

Both abutments and the powerhouse of the Buck Development are founded on interbedded thin quartzite and dark shale of the lowest member of the Erwin Quartzite Formation. When exposed, the thinly bedded, dark-banded quartzite of this member weathers to a rust color. It is of medium hardness and is less resistant to weathering and erosion than the next younger member of the formation, known as the Ridge-making member. This Ridge-making member forms the caps of Farmer Mountain and Round top, about 0.7 miles southwest of the dam, and extends eastward forming prominent ledges along the river upstream of the Buck powerhouse. These ledges create falls in the river upstream (Appalachian 1991a).

E.7.1.1.3 Mineral Resources

Sandstone and quartzite are quarried in Carroll County for production of roadstone, concrete aggregate, asphalt stone, and manufactured fine aggregate (Virginia Division of Mineral Resources 1998). In the Blue Ridge Province, copper has been found in massive-sulfide zinc- and copper-bearing pyrrhotite deposits in the Late Precambrian Ashe Formation in Carroll County (Virginia Division of Geology and Mineral Resources 2015a).

E.7.1.2 Soils and Sediment

Soil types in the vicinity of the Project are variable and reflect the diversity of parent materials, the local topography, and the physiographic position of landforms (Woodward 1932). Mapped soils in the Project vicinity are shown on Figure E.7-1. The soils surrounding the Byllesby and Buck developments vary in depth from shallow to deep and include residuum from sandstone, granite, or greenstone. In the immediate Project area, soils consist of the Weikert and Ramsey soils series and are typified by high erosion potential.

The Weikert series consists of shallow, well-drained soils formed in material that weathered from interbedded gray and brown acid shale, siltstone, and fine-grained sandstone on gently sloping to very steep areas on uplands. Slopes range from 0 to 100 percent and permeability is moderately rapid (USDA 2009).

The Ramsey series consists of shallow and very shallow, somewhat excessively drained soils that formed in residuum or colluvium weathered from sandstone or quartzite. They are dominantly on plateaus and upper slopes of mountains. Runoff is moderate to rapid, permeability is rapid, and slopes range from 3 to 70 percent (USDA 2001).

The construction of the Project over a century ago contributed to sediment deposition and accumulation in the reservoirs; however, the rate of sediment deposition has stabilized over recent decades. As summarized in Appalachian's sedimentation study performed during the Claytor Project relicensing (Appalachian 2008), the New River carries a large amount of sand as bed material and suspended (during high flows) sediment from its headwaters to Claytor Lake. These high sand loads have filled the reservoir created by Fields Dam, and deposits extend past the Highway 94 Bridge near Galax. Downstream of Fields Dam, the reservoir formed by Fries Dam is also characterized by high rates of sediment deposition in the bay upstream of Fries Dam, which requires periodic "flushing". Downstream of Fries Dam, high sediment loads and bed sedimentation continue through to the Byllesby-Buck Project. Watershed sedimentation modeling completed for the Claytor study concluded that the run-of-river Byllesby-Buck reservoirs have little retention capacity, and suspended sediments are carried downstream to the Claytor Project, where it is deposited into long-term storage.

Findings of the study performed for the Claytor relicensing included the following (Appalachian 2008):

- Sedimentation occurred throughout Claytor Lake but was most pronounced in bays, coves, and tributary inlets, where sediments included a mixture of coarser sand and gravel from upstream channel sources, fine sediments from upland soil erosion, and organic matter deposits from terrestrial and aquatic sources.

- Due to the prevalence of bedrock and stable shorelines in Claytor Lake, shoreline erosion was not found to be significant sediment source to the Claytor Project.

- The largest source of contemporary sediment was determined to be soil erosion from watershed disturbances, primarily from agricultural lands.

A sedimentation study, consisting of desktop assessment and a field survey of the reservoir to try to estimate current storage volume, was also conducted for the Fries Project relicensing (Kleinschmidt 2017). The results of this study demonstrated the difficulty of comparing impoundment storage capacity measurements due to error introduced by different survey methods: the results of the study

(presumably erroneously) suggested an increase in storage volume compared to historical surveys. The authors of this study report suggested that the Fries reservoir has likely reached a period of sediment balance, where sediment is passing the dam (Kleinschmidt 2017).

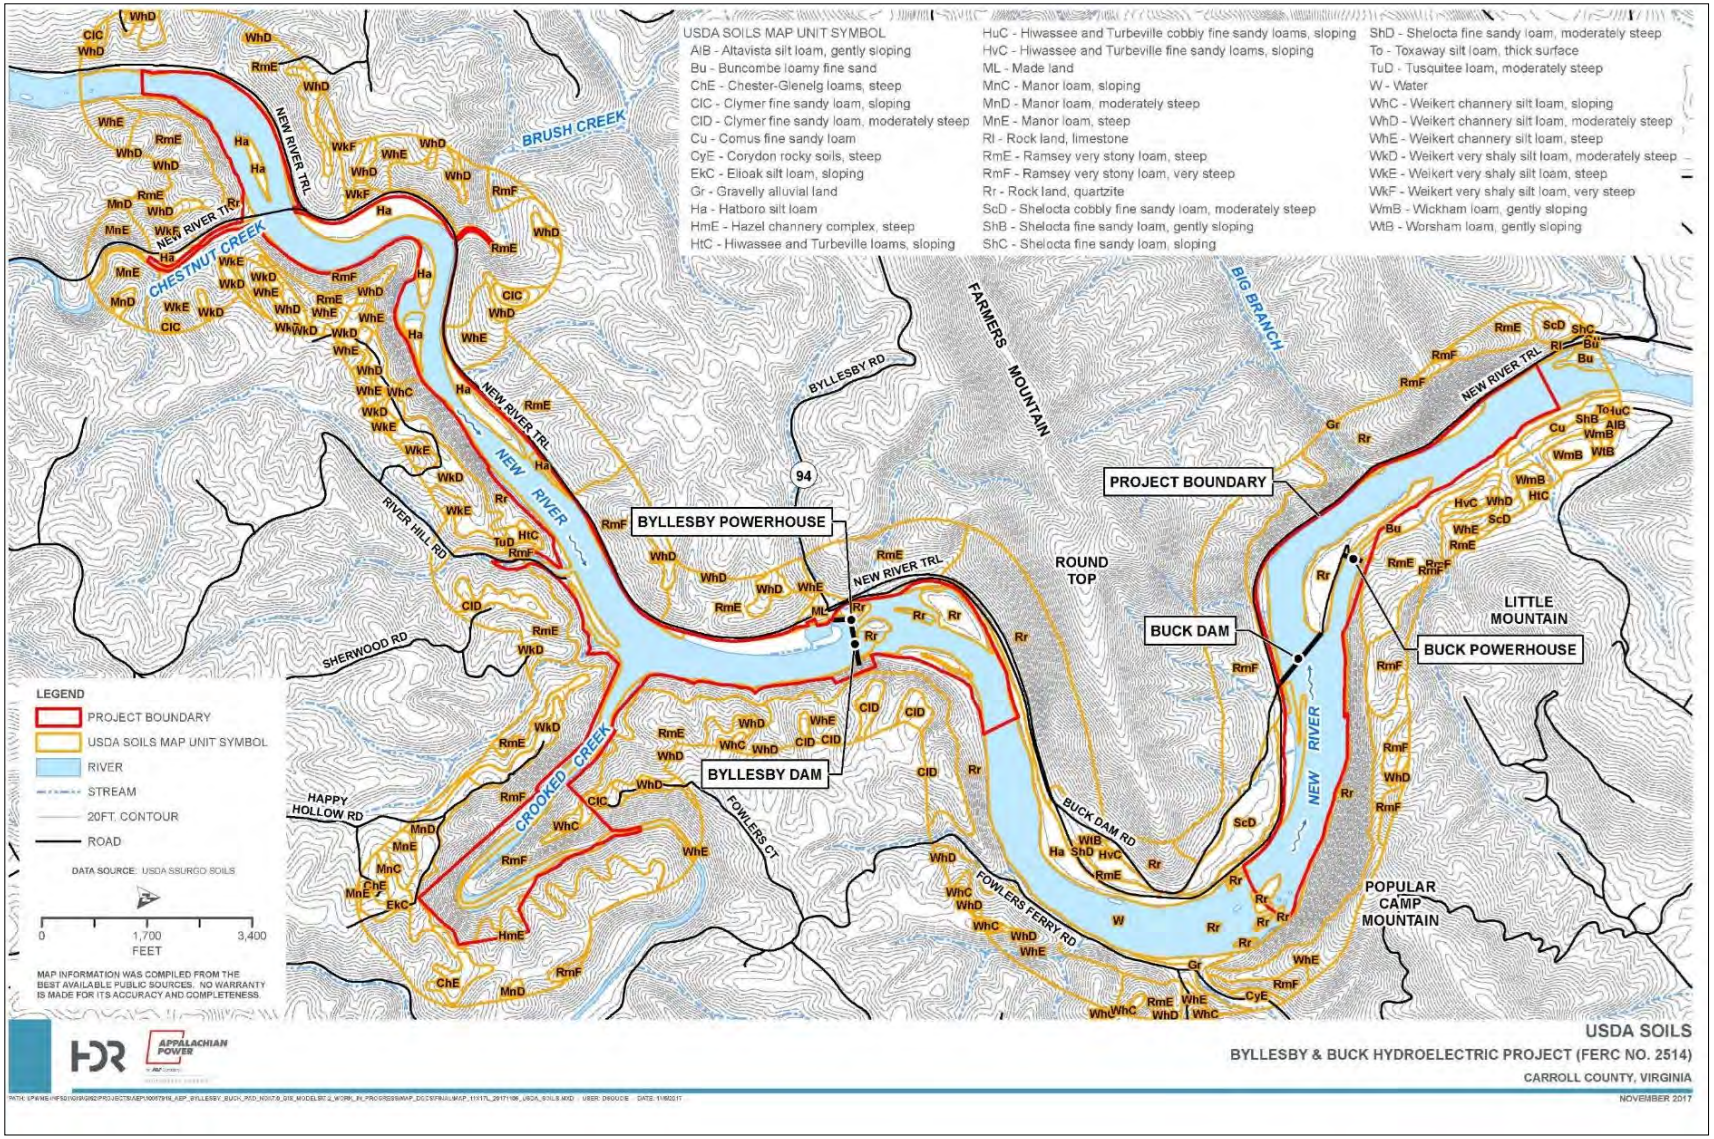

Figure E.7-1. Mapped Soils in the Vicinity of the Project

E.7.1.3 Shorelines and Streambanks

In the Project area, the New River has carved moderately steep valley walls, ranging in height from about 50 ft to several hundred ft (FERC 1994). Soils along the Project shoreline largely consist of steep to very steep, very stony Ramsey soil or quartzite rock. Because much of the shoreline is exposed bedrock, the limited extent and total thickness of soils limits the depth of erosion and slips, and such areas are expected to be limited to areas where vegetation cover is absent. Established vegetative cover is extensive along the shorelines of the Project, which helps to limit the extent and severity of erosion and movement of soils in the Project area that otherwise have high erosion potential. Additionally, accumulation of sediment along some portions of the Project shorelines has formed permanent riparian wetland communities, providing additional protection against shoreline erosion.

E.7.1.4 Seismicity

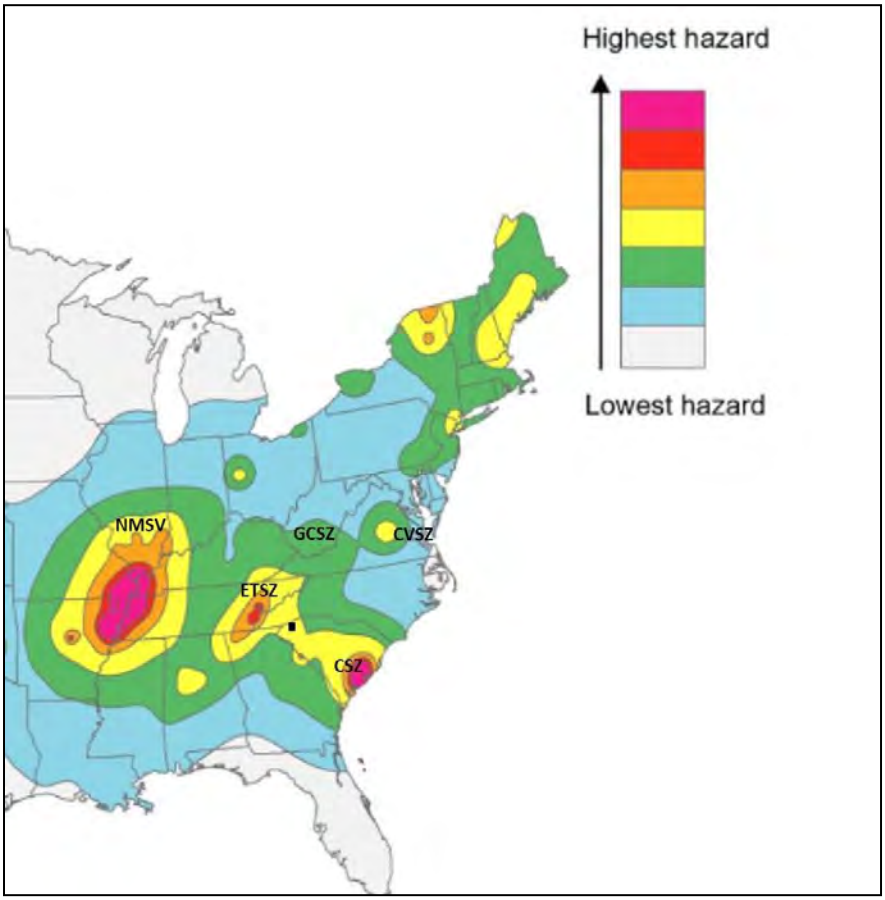
Most faults and fault sequences in the state of Virginia are considered inactive. Earthquakes that have occurred in the region are associated with three major seismic zones including the Central Virginia Seismic Zone (CVSZ), the Giles County Seismic Zone (GCSZ), and the Eastern Tennessee Seismic Zone (ETSZ). The GCSZ borders the state of West Virginia in southwestern Virginia and extends into the New River Valley, which includes Carroll County (Virginia Division of Geology and Mineral Resources 2015b). The Project is located to the east of the GCSZ and southwest of the CVSZ.

The Central Virginia Earthquake of August 23, 2011 (moment magnitude scale [$M_{w]}$ 5.7 - 5.8) was the largest earthquake in the central and eastern United States since the 1886 Charleston, South Carolina earthquake (estimated M_w 6.8 - 7.0). The earthquake occurred on a north or northeast-striking plane with reverse faulting within the CVSZ. The CVSZ is located in the Appalachian Piedmont Province between Richmond and Charlottesville, Virginia (see Figure E.7-2). The depth of the earthquakes ranges from near surface to 12 kilometers, placing them above the Appalachian detachment (Chapman 2015) in contrast to the Eastern Tennessee Seismic Zone, where earthquakes occur below the detachment. The CVSZ has produced small and moderate earthquakes since at least the 18th century. The previous largest historical shock from the CVSZ occurred in 1875. Additionally, a magnitude VIII event (Modified Mercalli Intensity Scale) occurred in Giles County, Virginia in May of 1897. It was felt in the Project area with chimneys shaken down in Roanoke.

More recently, a 5.1-M_w magnitude occurred on August 9, 2020 with an epicenter near Sparta, approximately 25 miles southeast of the Project and just south of the Virginia-North Carolina border (Figure E.7-2). The earthquake caused damage to over 500 buildings and other infrastructure (Hill 2020

). It has not been determined whether the isolated event is associated with the GCSZ or the CVSZ (or neither).

Regional seismic activity in the area is considered low, with low to moderate peak ground acceleration values as determined by the USGS (USGS 2018).



Note: GCSZ = Giles County Seismic Zone; ETSZ = East Tennessee Seismic Zone; CVSZ = Central Virginia Seismic Zone; CSZ = Charleston Seismic Zone; NMSZ = New Madrid Seismic Zone. Project location indicated by black square (source: USGS)

Figure E.7-2. Relative Seismic Hazard in the Southeastern U. S. with Identified Seismic Zones (modified from USGS 2018)

E.7.2 Environmental Analysis

E.7.2.1 Studies in Support of the Current Licensing

E.7.2.1.1 Shoreline Survey

Appalachian conducted a Shoreline Stability Assessment for the Project in June 2021 as one of the eight studies for the relicensing effort. The study area for the Shoreline Stability Assessment Study

includes the reservoir shorelines, bypass reaches, and tailrace areas downstream of the Byllesby and Buck powerhouses. The goals and objectives of the Shoreline Stability Assessment Study were to:

- Survey each development's reservoir, bypass reach, and tailrace area to characterize the shoreline, with the focus on erosion or shoreline instability using the Bank Erosion Hazard Index (BEHI; WVDEP 2015);
- Inventory, map, and document any areas of erosion or shoreline instability; and
- Prioritize any areas where remedial action or further assessment may be needed.

A desktop analysis was followed by field confirmation of shoreline areas within the Study Area, including reservoirs, bypass reaches, and tailraces that were identified in the desktop analysis as requiring confirmation or additional investigation.

Shorelines were assessed in the field for susceptibility to erosion, and for need and potential for remediation. For each area observed, vegetative cover, quantity of material, height, and slope of bank, existing erosion control mechanisms, soil or rock type, composition, and thickness of various bank materials or strata, and other relevant data were noted. A GPS was used to identify and record areas of erosion with photograph documentation. Geographic Information System (GIS) maps are being produced to characterize the banks of the study area.

An analysis of erosion potential for the areas identified within the study area is being conducted. Recommendations for minimizing the effects of bank erosion from Project operations and/or enhancing bank stability are being assessed. A report characterizing bank erosion potential and stability in the study area is being prepared for filing with the USR. The final report will include an analysis of the degree of susceptibility to erosion for all shorelines in the study area.

Based on preliminary review of study observations, no areas of significant shoreline erosion or areas requiring mitigation have been identified. Final study results are expected to provide adequate information to assess shoreline-erosion effects by Project operations. This section will be updated in the FLA.

E.7.2.1.2 Turbidity Study

Appalachian is conducting a study to evaluate the potential impact that Project operations, in particular drag rake operations, have on turbidity concentrations in the Project tailraces. The study is planned to be conducted over a one-week period at the end of September / early October 2021 under relatively low flow conditions. During this study period, a Hydrolab data sonde equipped with a turbidity sensor

will be installed at each of the locations listed below (which coincide with the continuous monitoring locations shown in Figure E.8 1) to continuously record turbidity concentrations (in Nephelometric turbidity units) at 5-minute intervals.

- One location in the upstream extent of the Byllesby reservoir (to characterize background turbidity levels)
- One location in the Byllesby forebay (approximate mid-depth)
- One location in the Byllesby tailrace below the powerhouse
- One location in the Buck forebay (approximate mid-depth)
- One location in the Buck tailrace below the powerhouse

During this study period, Appalachian will operate the generating units and drag rakes at each Project under a pre-determined range of normal operating regimes. Turbidity data collected will be evaluated against drag rake operation and powerhouse generation in an effort to help determine any differences in downstream turbidity concentrations resulting from station operations versus naturally occurring background conditions. The turbidity study is ongoing and results will be provided in the USR and summarized in the FLA.

E.7.2.2 Project Impacts on Geology, Geomorphology, and Soils

In SD3, FERC identified two environmental issues related to geologic and soils resources to be addressed in its NEPA document:

- Effects of continued project operation and maintenance on shoreline erosion in the impoundments at each development (Buck and Byllesby).

- Effects of continued project operation and maintenance (including localized maintenance dredging via the project's drag rakes and more infrequent impoundment-wide dredging after large storm events) on sedimentation in the project impoundments and sediment transport through each development, including the potential for the remobilization of PCBs.

Appalachian anticipates that the existing run-of-river mode—including stable reservoir surface elevation—at the Project, in combination with the vegetated and undeveloped nature of the shorelines in the Project Boundary, provide protection against bank erosion. Periodic drawdowns for maintenance work do have the potential to contribute to additional shoreline erosion through localized bank failure and sloughing. Additionally, if a rain event would occur during a scheduled drawdown, the lower banks of the shoreline, which are typically covered by water, could be subject to erosion. Areas of significant

shoreline erosion were not observed during the Shoreline Stability Assessment performed for this relicensing.

Sedimentation in most reservoirs is limited to specific areas based on morphology and flow and in some cases, these areas of deposition have the potential to create beneficial habitat (e.g., riparian wetlands). Some of the wetland areas within the Project Boundary (e.g., the large wetland upstream of Byllesby Dam) have formed or expanded due to localized areas of sediment deposition.

Based on the results of the above-referenced sedimentation study conducted for the Claytor relicensing (Appalachian 2008), most of the sediment load that enters the Byllesby and Buck developments is expected to pass through the Project and be deposited downstream. The sediment that does accumulate at the Project reservoirs has resulted in minor loss of reservoir gross storage capacity, but this does not normally affect operation, hydraulic capacity, or generation. Over time, however, and at specific areas such as the dam and intake, sedimentation may affect specific Project operations. Historically, Appalachian has dredged accumulated sediment on an as-needed basis. Significant maintenance dredging was performed at the Project in 1997. During this maintenance dredging project, accumulated sediment along a 250-ft by 350-ft area along the upstream face of the dam was hydraulically dredged to reestablish the intake area and maintain operability of the auxiliary spillway. The dredged material was used to create a new 6-acre area of emergent marsh. All work was conducted in accordance with the terms and conditions of permits and approvals by USACE and the VDEQ, as further authorized by standard FERC license article 12. Prior to dredging, sediment was subject to sediment toxicity testing to confirm the appropriateness of placing dredged materials in the proposed upstream mitigation site, as required by the VWP Permit issued for this maintenance activity. The most recent dredging activity at the Project was conducted at the Byllesby Development forebay in 2014 following flooding that occurred at the Project in 2013. This work was also conducted pursuant to the terms and conditions of approvals and permits issued by USACE and VDEQ, as authorized by FERC license article 12. Materials removed as part of dredging were beneficially reused offsite after being tested for various constituents. Based on visual observations, sediment that accumulates in the Byllesby forebay is sandy. The risk of PCB adsorption generally decreases with sediment particle size (Krauss and Wilcke 2002); this, combined with analyses from previous sediment sampling conducted in association with dredged material disposal, supports that sediment transport through the Project presents a low risk for PCB remobilization.

The recent installation of inflatable Obermeyer crest gates is expected to reduce the frequency and duration of maintenance drawdowns, thereby minimizing the resultant potential for shoreline erosion.

During the conduct of relicensing studies over the course of this relicensing, Appalachian's consultants had the opportunity observe this reach of the New River under a range of flow conditions, including periods following significant precipitation events. Above, throughout, and below the Project area, turbidity levels (based on visual appearance) significantly increase during and following rainfall-runoff events and recede in between events. This phenomenon of spikes in river turbidity due to precipitation can also be seen in the lower New River (see, for example, turbidity data available for the past two years at USGS gage 03185400, New River at Thurmond, WV), and in rivers and streams throughout the region. As described above, Appalachian is in the process of conducting a turbidity study to assess the potential impacts of continued operation of the Project's drag rakes on sedimentation in the Project impoundments and sediment transport through each development. While results and observations from this study are still pending, Appalachian expects that the study will demonstrate that the impact of resuspension and transport of sediment due to operation of the trashracks is negligible relative to background turbidity levels and periodic precipitation events.

The Licensee does not anticipate that operation and maintenance of the Project over the new license term will have any short- or long-term, unavoidable, adverse impacts on geology, geomorphology, and soils.

E.7.3 Protection, Mitigation, and Enhancement Measures Proposed by the Applicant, Resource Agencies, and/or Other Consulting Parties

Appalachian proposes to continue operating the Byllesby and Buck developments as they are presently operated, including run-of-river operations and maintenance of existing vegetated and buffer areas.

Appalachian will continue to evaluate opportunities to improve sediment transport through the Project's forebay and intake areas, to reduce deposition and the frequency of periodic maintenance drawdowns. Coordination of any necessary future dredging and disposal with USACE and VDEQ will be performed pursuant to standard license article 12 and any additional permits or approvals issued for such activities. Any ground disturbance of shorelines or streambanks will be subject to the erosion control protections and requirements of the new license and the VWP Permit.

Appalachian plans to evaluate the need and benefit for any additional operational PM&E measures to address findings from the ongoing turbidity study. If such measures are identified, they will be proposed in the FLA.

Preliminary results of the Shoreline Stability Assessment indicated that banks are stable and do not show signs of mass wasting or slumping. The Wildlife Management Plan (WMP) required by Article

408 of the existing license and implemented by Appalachian is intended, in part, to provide a means of visually monitoring for bank erosion. No signs of shoreline erosion have, however, been identified during this annual visual monitoring. Appalachian does not propose to continue the WMP during the term of the new license.

Appalachian does not believe that additional PM&E measures beyond the standard license article requirements are required for the protection of geology, geomorphology, and soils.

E.8 Water Use and Quality

E.8.1 Affected Environment

E.8.1.1 Drainage Area

The drainage area for the Byllesby development is 1,310 square miles. The drainage area for the Buck Development is 1,320 square miles. The USGS gage 3165500 (New River at Ivanhoe, VA) is located approximately 2.8 miles downstream of the Buck Project; the drainage area at this gage is 1,350 square miles.

E.8.1.2 River Flows

New River streamflow characteristics are typical of the southeast; river flows are typically higher in the winter and spring and lower in the summer and fall. For the purposes of this document, flows at the Project were estimated from the upstream USGS gage 03164000, New River Near Galax, VA, and prorated for the drainage areas at the Project developments. The estimated daily flows are considered to be representative of discharge from run-of-river operation of the Project.

Flow statistics for the Byllesby and Buck developments are shown in Table E.8-1 and Table E.8-2, respectively. Monthly daily average flows for the Project for the period of record range (at Byllesby) from 1,453 cfs to 3,068 cfs (Table E.8-1). A significant historic flood for which streamflow data is available occurred in August 1940 with a flow of 141,000 cfs

Annual and monthly flow duration curves have been developed for the Project using flow data from the upstream USGS gage 03164000 (prorated for the drainage area of the Project developments). These flow duration curves are included in Exhibit B of Volume I of this license application.

Table E.8-1. Byllesby Project Daily Flow Data (1996-2020)

Period	Minimum (cfs)	90% Exceedance (cfs)	Average (cfs)	10% Exceedance (cfs)	Maximum (cfs)
January	393	949	2,553	4,493	32,701
February	582	1,164	2,869	4,858	26,588
March	762	1,372	2,833	4,423	16,205
April	1,067	1,493	3,068	4,572	23,386

E.8.1.3 Water Uses

Waters impounded by the Byllesby-Buck Project are used for purposes of electric generation and for public recreation. There are no known discharges to or withdrawals from the New River within the Project boundary or between the Byllesby and Buck developments. Existing instream flow uses of waters of the New River within the Project boundary include various recreational activities (e.g. fishing and boating) and hydroelectric generation.

E.8.1.4 Water Quality

E.8.1.4.1 Approved Water Quality Standards

Existing relevant and reasonably available information regarding water quality in the Project vicinity was presented in Section 5.3 of the PAD (Appalachian 2019). The PAD included historical water quality data collected by the USGS and VDEQ. The data presented in the PAD indicates that temperatures and DO concentrations did not differ between impoundments and tailraces during collection efforts, and no evidence of thermal stratification was observed in either impoundment. Data from the historical studies also demonstrated that the Project waters meet the state water quality standards, including temperature maximums and DO minimums.

The VDEQ issues Virginia Pollutant Discharge Elimination System permits for all point source discharges to surface waters, to dischargers of stormwater from Municipal Separate Storm Sewer Systems, and to dischargers of stormwater from industrial activities. The VDEQ is responsible for carrying out the mandates of the State Water Control Law as well as meeting federal obligations under the CWA (VDEQ 2017). Waters in the New River Basin are classified in 9VAC25-260-540. The New River in the vicinity of the Project is designated as Class IV (Mountainous Zone) (Table E.8-3). Numerical criteria for DO, pH, and maximum water temperature for these waters are identified in 9VAC25-260-50 and are summarized in Table E.8-4. In accordance with 9VAC25-260-50, these water quality criteria do not apply when flows are below the lowest 7-day average flow expected to occur once every 10 years (i.e., the 7Q10 flow).

Table E.8-3. Classification of Project Area Waters – New River

Section	Class	Special Standards	Section Description
2	IV	v, NEW-5	New River and its tributaries, unless otherwise designated in this chapter, from the Montgomery-Giles County line upstream to the Virginia-North Carolina state line.
2l	IV	PWS	New River and its tributaries inclusive of the Wythe County Water Department's Austinville intake near the Route 636 bridge, and the Wythe County Water Department's Ivanhoe intake on Powder Mill Branch just upstream of the Wythe-Carroll County line to points 5 miles above the intakes.

v – The maximum temperature of the New River and its tributaries (except trout waters) from the Montgomery-Giles County line upstream to the Virginia-North Carolina state line shall be 29 degrees Celsius (°C) (9VAC25-260-310).
NEW – nutrient-enriched waters; only includes New River and its tributaries, except Peak Creek above Interstate 81, from Claytor Dam upstream to Big Reed Island Creek (Claytor Lake) as per 9VAC25-260-350.
PWS – public water supply.

Table E.8-4. Numeric Water Quality Criteria for Class IV Waters

Parameter	Standard
Minimum DO	4.0 milligram per liter (mg/l)
Daily Average DO	5.0 mg/L
pH	6.0 – 9.0
Maximum water temperature	29°C*

*The maximum temperature of the New River and its tributaries (except trout waters) from the Montgomery-Giles County line upstream to the Virginia-North Carolina state line shall be 29°C (9VAC25-260-310).

Multiple segments of the New River are listed as impaired for aquatic life or recreation uses due to *E. coli* concentrations. However, the source of *E. coli* is not associated with the Project and it is expected that continued operation of the Project will have no effect on *E. coli* concentrations in the New River.

E.8.1.4.2 Impaired Waters

The VDEQ develops and maintains a listing, referred to as a Section 303(d) List, of all impaired waters in the state, which provides details on the pollutant causing the impairment and the potential sources of each pollutant per requirements of the CWA and Virginia Water Quality Monitoring, Information, and Restoration Act. The VDEQ is required to develop and implement a Total Maximum Daily Load (TMDL) for waters listed on the Section 303(d) list. A TMDL is used to determine the total amount of a pollutant that a waterbody can handle without resulting in the impaired status of that waterbody (VDEQ 2017b).

Project waters listed as impaired in the 2020 Section 303(d) Water Quality Assessment Integrated Report include:

- Assessment Unit ID VAS-N08R_NEW03B98 – from Buck Dam downstream 0.9 miles. Recreational uses are impaired due to *E. coli* associated with livestock grazing and feeding operations. A TMDL is required for this reach of the New River (VDEQ 2017a).
- Assessment Unit ID VAS-N08R_NEW02B00 – a 5.0-mile reach of the mainstem public supply segment for Austinville from Buck Dam tailwaters downstream to the confluence with Mill Creek. Recreational uses are impaired due to *E. coli*.
- Assessment Unit ID VAS-N07R_CRK01A98 – a 12.1-mile reach of lower Crooked Creek from the confluence with the New River. Recreational uses are impaired due to *E. coli* and fecal coliform from unrestricted cattle access and other unknown sources. A TMDL is required for Crooked Creek (VDEQ 2017a).
- Assessment Unit ID VAS-N06R CST01A94 – an 8.7-mile reach of lower Chestnut Creek from the confluence with the New River. Aquatic life is impaired for benthic macroinvertebrate bioassessments; sedimentation and siltation were also observed. Recreation uses are impaired due to *E. coli* (VDEQ 2017a). A sediment and bacteria TMDL for Chestnut Creek was finalized in 2015 (The Virginia Tech Department of Biological Systems Engineering 2015).
- Assessment unit ID VAS-N08R_NEW01L98 – a 3.1-mile reach in the mainstem New River extending from Buck Dam upstream to Byllesby Dam. Recreational uses are impaired due to *E. coli.*

E.8.1.4.3 Historical Water Quality Data from the Project Study Area

From May through October 1989, in support of the previous relicensing, DO and water temperature profiles were measured by Appalachian at four transects, one each located above and below the two developments:

- At the Byllesby Development, mean reservoir temperatures ranged from 11.3 to 25.1°C. Mean DO ranged from 6.9 to 10.1 mg/L in the reservoir and from 7.1 to 10.9 mg/L in the powerhouse tailrace, and percent saturation was never below 78 percent for any measurement.
- At the Buck Development, mean reservoir temperatures ranged from 10.9 to 25.3°C. Mean DO ranged from 6.7 to 11.1 mg/L in the reservoir and from 7.0 to 11.6 mg/L in the powerhouse tailrace, and percent oxygen saturation was never below 77 percent for any measurement.
- No evidence of thermal stratification was found in either reservoir.

- For the Byllesby reservoir, at depths up to about 6 meters (m), the maximum surface-to-bottom temperature differential was 2.3°C, and the maximum DO differential was 1.2 mg/L.
- For the Buck reservoir, at depths up to about 4.5 m, the maximum surface-to-bottom temperature differential was 1.0°C, and the maximum DO differential was 1.5 mg/L (Appalachian 1991a).

Additional water quality data was collected in the Project reservoirs, as well as free-flowing riffle/run areas above and below each development, as part of a fishery survey conducted by Appalachian from May to October 1990. These data are summarized in Appalachian (1991b) and below:

- DO and temperature did not significantly vary across the sampling locations.
- Conductivity varied very little, either spatially across the locations or temporally over the study period. Measurements were typically low, ranging from 46-60 micromhos per centimeter, with the highest measurements recorded in September (65-138 micromhos per centimeter).
- Secchi depth readings at the reservoir sampling locations did not vary significantly on a spatial scale, with mean values ranging from 1.33 m at the upper Buck reservoir to 3.08 m at the upper Byllesby reservoir. Minimum water clarity values were recorded in October, and maximum clarity was recorded in October.

More recently, water quality data have been collected approximately 3 RM downstream of the Buck Dam at the USGS 03165500 (New River at Ivanhoe, VA) gage. Due to the proximity of this monitoring location to the Project, the water quality data is expected to be indicative of the characteristics of Project outflows. Daily mean water temperature and specific conductance data were collected from March 2007 to September 2008; daily mean water temperatures ranged from 0.3°C in to 28.9°C and were below the maximum state criterion. Daily mean specific conductance ranged from 55 microsiemens per centimeter (µS/cm) to 108 µS/cm.

The VDEQ has also collected water quality data approximately 2 RM downstream of Buck Dam at Site 9-NEW127.49. Water temperature, DO, pH, and specific conductivity data were collected at a depth of approximately 0.3 m from 1992 to 2017. Water temperatures ranged from 0.0 to 28.7°C and were below established state criterion. DO concentrations ranged from 5.3 mg/l to 14.8 mg/l and were well above the minimum state criterion. The pH ranged from 5.9 to 8.9 and were also within the state criteria range, except for a single day in December 1999. Specific conductivity ranged from 20 to 80 µS/cm.

On August 29, 2019, a site visit was conducted by HDR for Appalachian to collect water quality data and evaluate field logistics associated with potential water quality monitoring locations for the Byllesby and Buck developments. During the site visit, a calibrated multiparameter water quality data sonde was used to collect depth profiles in each development's forebay and discrete measurements were taken in each development's tailrace. Streamflow during the site visit was approximately 1,500 cubic feet per second (cfs) measured at USGS gage 03165500, which is typical of average flow conditions in August at this location. During the site visit, the Byllesby forebay elevation was in the normal operating range,[3] however, the Buck forebay elevation was approximately 9 ft lower than the normal operating range[4] to facilitate construction activities associated with installation of the new Obermeyer gates.

All water quality measurements during the site visit were within applicable Virginia state water quality standards. As Figure E.8-1 and Figure E.8-2 indicate, the depth profiles in each forebay did not show any significant difference in water quality from top to bottom or laterally. The tailrace measurements were reflective of the water quality in each forebay.

[3] Normal operating range for the Byllesby impoundment is between 2,078.2 – 2,079.2 ft.

[4] Normal operating range for the Buck impoundment is between 2,002.4 – 2,003.4 ft. During the August 29, 2019 water quality sampling site visit, the forebay elevation was approximately 1,994 ft; or approximately 9 ft below the normal operating range.

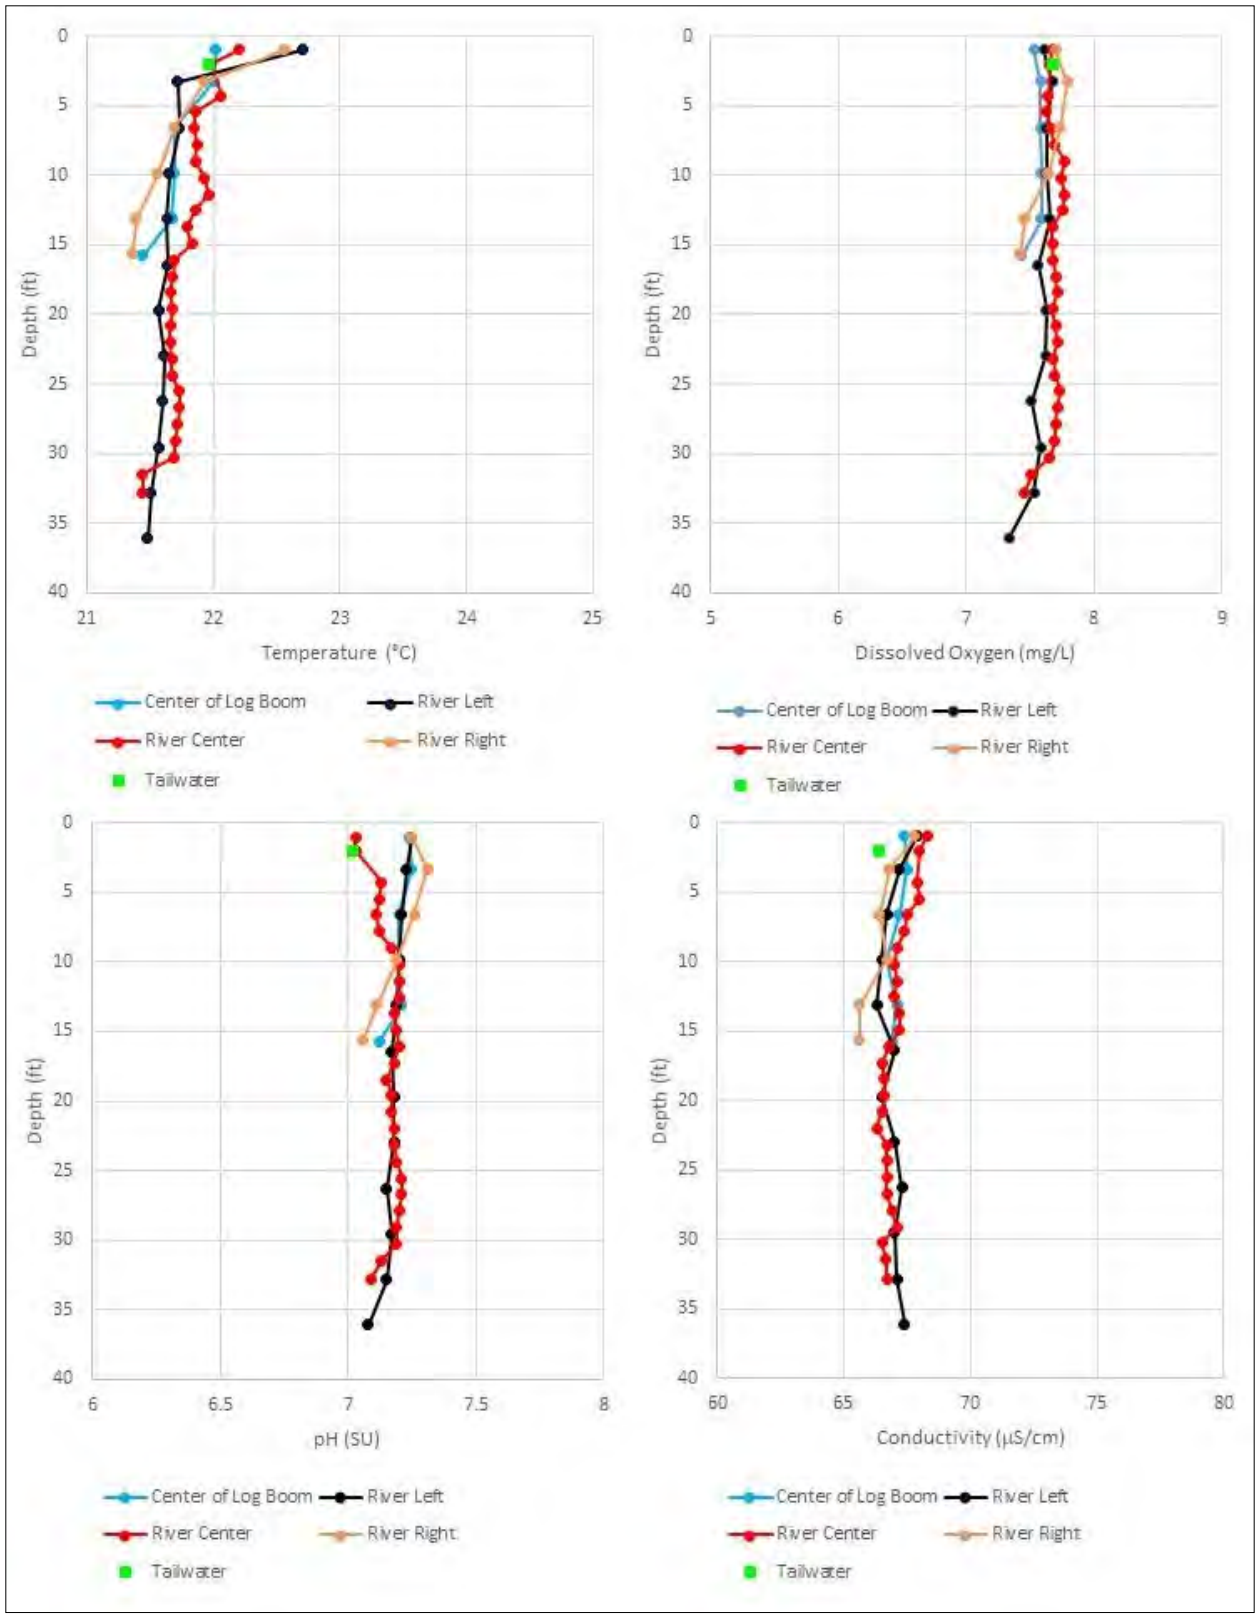

Figure E.8-1. Water Quality Parameters for Byllesby (August 29, 2019)

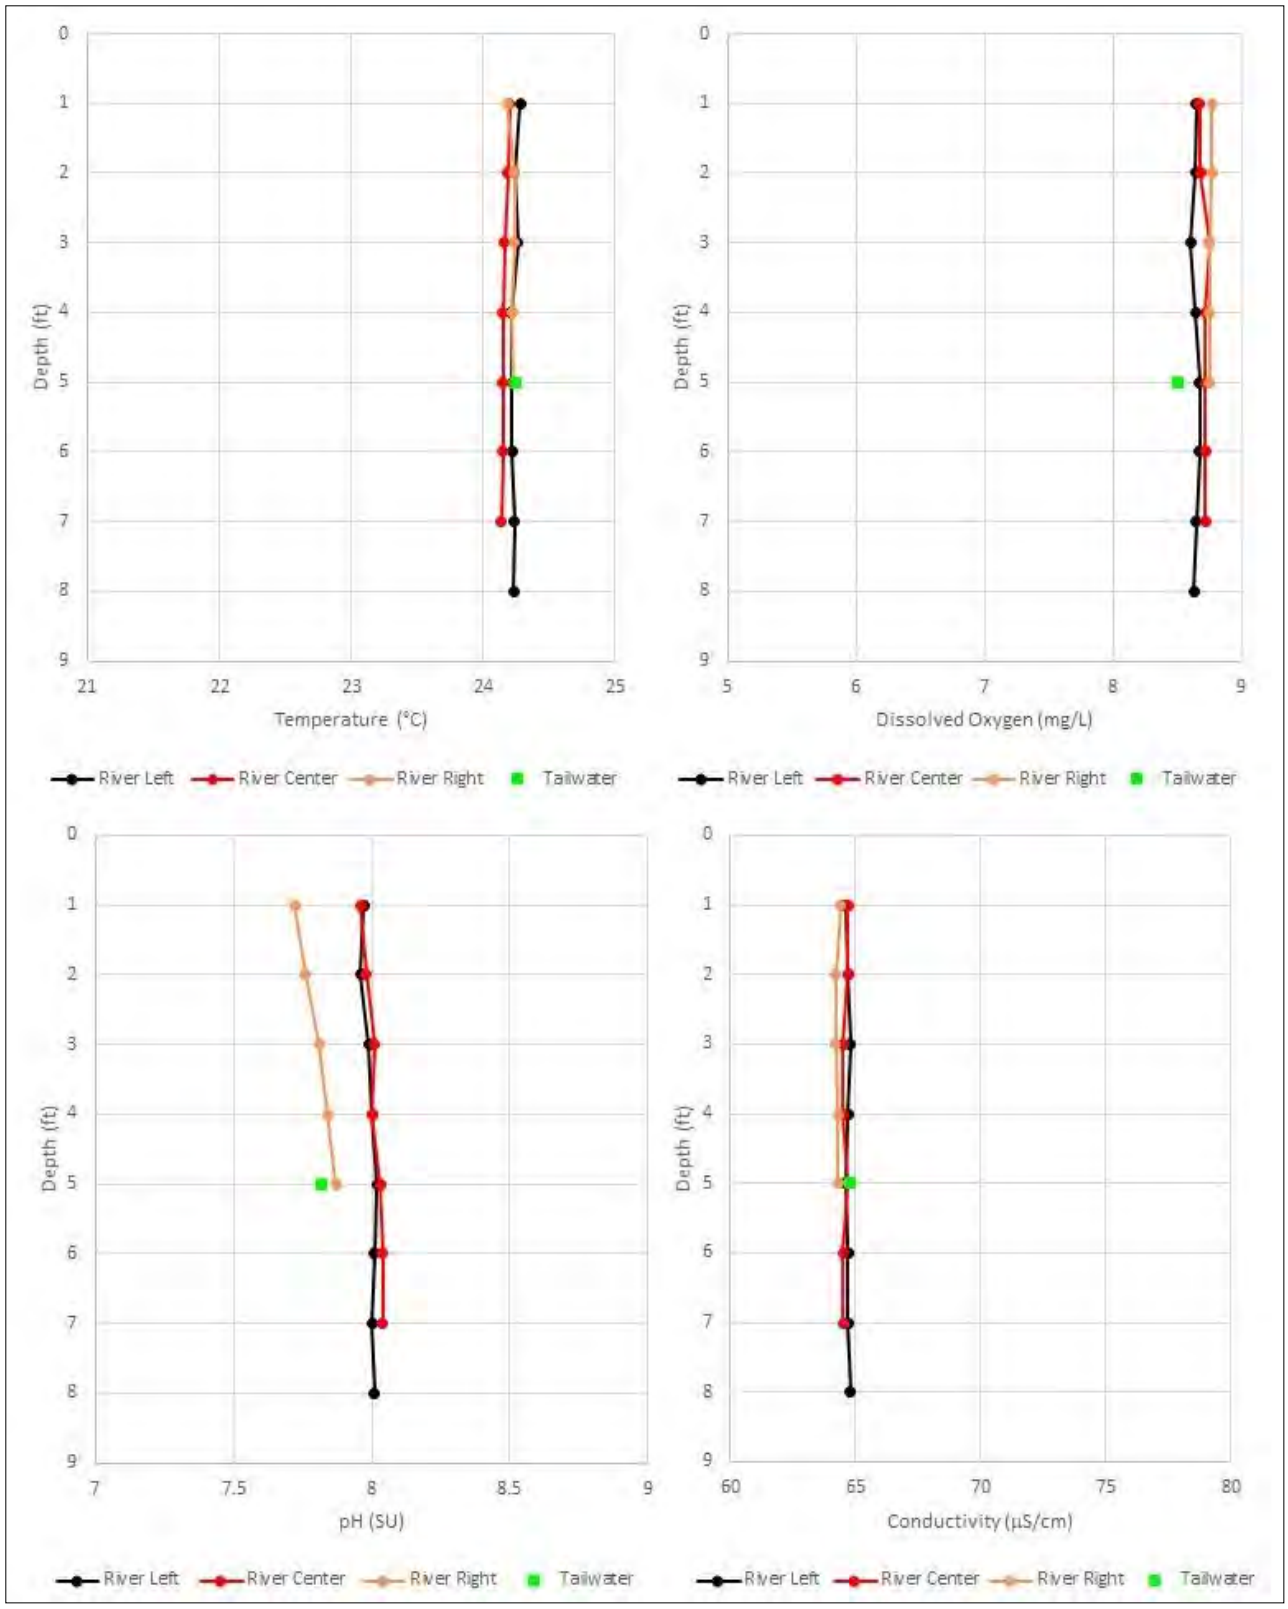

Figure E.8-2. Water Quality Parameters for Buck (August 29, 2019)

E.8.2 Environmental Analysis

E.8.2.1 Studies in Support of the Current Relicensing

In support of the current relicensing, Appalachian conducted a Water Quality Study in 2020 and 2021. The specific objectives and a summary of the methods and results of the Water Quality Study are included below.

- Gather baseline water quality data sufficient to determine consistency of existing Project operations with applicable Virginia state water quality standards and designated uses (VAC Chapter 260).
- Provide data (temperature and DO concentration) to determine the presence and extent, if any, of thermal or DO stratification in the Byllesby and Buck impoundments.
- Provide data to support a Virginia Water Protection Permit application (CWA Section 401 Certification).
- Provide information to support the evaluation of whether additional or modified PM&E measures may be appropriate for the protection of water quality at the Project's developments.

The Water Quality study area is shown on Figure E.8-1. As the Water Quality Study is still on-going, additional details and discussion will be provided in detail in the USR and summarized in the FLA.

2020 Water Quality Monitoring

HDR deployed water quality instruments (i.e., DO and water temperature sondes) at Buck the week of August 17, 2020. This same week, due to high flow conditions and continuous flow release at the dam through the damaged flashboard section throughout Q3 2020, water quality instrumentation at Byllesby was only installed at the tailrace location. Therefore, there were five locations monitored at the Buck Development (two locations in the forebay [one near surface and the other near bottom], one location in the tailrace, two locations in the bypass reach [upstream and downstream] and one location at the Byllesby Development (one location in the tailrace). During the initial deployment and subsequent download events, discrete multi-parameter water quality measurements of temperature, DO concentration, pH, and specific conductivity were collected at each monitoring location using a Hach Hydrolab® MS5 (Hydrolab). For the tailrace and bypass reach monitoring locations, Hydrolab water quality data were collected at one location within the water column at a depth similar to the sondes. Profile data were collected at 1-ft intervals[5] using the Hydrolab for the Buck forebay monitoring location to document temperature and DO stratification at the time of the data sonde downloads. D

[5] During the August 17, 2020 water quality sampling event, profile data were collected at 2-ft intervals; a 1-ft interval was used during subsequent water quality sampling events.

iscrete water quality data collections occurred concurrent with deployment and downloads of the continuous data loggers.

Data were downloaded from instrumentation at Buck during the field efforts from September 8 - 10, 2020, and at Byllesby and Buck from October 7 – 8, 2020, after which time data collection instruments were removed per the schedule in the RSP. Field staff downloaded data from sondes at each monitoring location using a data shuttle or directly to a laptop computer. Sondes were cleaned, checked for operation, calibration, and battery life; and adjusted as necessary based on manufacturer's specifications.

Continuous and discrete water temperature data at the forebay and tailrace locations at Buck are provided in the Preliminary Water Quality Study Report filed with the ISR. Water temperatures at these locations were similar to those recorded at the Byllesby tailrace. The Buck forebay and tailrace monitoring locations were within 0.5ºC of each other for most of the study period, which is reflective of run-of-river operations. In the Buck bypass reach, daily temperature fluctuations at the downstream monitoring location were approximately twice that observed at the upstream monitoring location. While both monitoring locations are in relatively small pools, the upstream location is shaded more of the day compared to the downstream location, thus daily temperature cycles at the upper location are lower in magnitude.

Continuous and discrete DO concentration data at the Buck forebay and tailrace monitoring locations are also included in the Preliminary Water Quality Study Report filed with the ISR. All measurements were greater than the 5.0 mg/l daily average DO standard. Daily fluctuations in DO concentrations were less than 1.0 mg/l during the study except for September 4 – 11, 2020 when the daily fluctuation increased to the 1.0 – 2.0 mg/l range at the forebay monitoring locations.[6] Similar to water temperature, there is little (i.e., typically < 1.0 mg/l) to no difference in DO concentrations between the forebay surface and bottom locations; indicating little to no stratification of DO concentrations throughout the forebay water column. DO concentrations in the tailrace were generally higher (by up to 1.0 mg/l) compared to the forebay monitoring locations. This suggests that unit generation and the trash sluice gate operation increase aeration into the tailrace. Tailrace concentrations typically fluctuated approximately 0.25 mg/l between day and night. All Buck bypass reach DO concentrations were greater than the 5.0 mg/l daily average DO standard with daily fluctuations of up to 1.0 mg/l for the upstream location and up to 3.0 mg/l at the downstream location. DO concentrations are influenced b

[6] Flows recorded at the Ivanhoe USGS flow gaging station from September 4 – 11, 2020 were relatively low and stable (compared to the weeks preceding and following) which likely contributed to slightly increased fluctuations in DO concentrations during this period.

y water temperatures and because the upstream monitoring location is shaded more of the day (compared to the downstream monitoring location), thus the daily fluctuation in DO concentrations is less at the upstream location.

At the Buck forebay monitoring location, the variation in pH (measured in standard units) was very small (between 7.3 and 7.7) and there was little to no stratification between the reservoir surface and bottom measurements. Discrete pH measurements at each monitoring location during the initial instrument deployment and two download events were between 7.2 and 8.9 which meets the state water quality standard.

Specific conductivity at the Buck forebay monitoring location varied each sampling event, but concentrations were typically the same from reservoir surface to bottom and ranged from 53 – 61 µS/cm over three sampling events during the study period. While there is no state standard for specific conductivity, concentrations less than 500 µS/cm are generally considered to be suitable for aquatic species in southern Appalachian streams (USEPA 2020). These results are consistent with specific conductivity measurements during the August 29, 2019 site visit and the results of other nearby historical studies and data collection efforts (NWQMC 2020; Stantec 2016) indicating a long-term, relatively consistent range of conductivity in the Project area.

Overall, water quality data collected during the August 29, 2019 site visit (at Byllesby and Buck) and 2020 study period (at Buck) indicated little to no thermal or DO stratification at the forebay monitoring locations. Water temperatures typically varied less than 0.5ºC from reservoir surface to bottom and DO concentrations typically varied less than 1.0 mg/l from reservoir surface to bottom. While the data sondes were not deployed until August 17, 2020, water temperature and DO concentrations were typical of warmer summer conditions.

2021 Water Quality Monitoring

HDR deployed continuous DO and water temperature sondes at the Byllesby Development on June 15 - 16, 2021. Water quality instruments were installed at six locations including three locations in the forebay (upper, mid-depth, and lower water column), one location in the tailrace, one location in the bypass reach, and one location near the upstream end of the Byllesby impoundment. During the initial deployment and subsequent download events, discrete multi-parameter water quality measurements of temperature, DO concentration, pH, and specific conductivity were collected at each monitoring location using a calibrated Hydrolab. For the tailrace, bypass reach, and upstream monitoring locations, Hydrolab water quality data were collected at one location within the water column at a depth similar to the sondes. Profile data were collected at 2-ft intervals using the Hydrolab for the Byllesby forebay monitoring location to document temperature and DO stratification at the time of the data

sonde downloads. Discrete water quality data collections occurred concurrent with deployment and downloads of the continuous data loggers.

Data were downloaded from instrumentation at Byllesby approximately every 2 – 3 weeks[7] until removal in early October 2021[8]. Download events occurred on the following dates, with additional data collection presently scheduled to approximately coincide with the filing of this draft license application.

- June 28, 2021
- July 14, 2021
- July 27 – 29, 2021
- August 25, 2021
- September 7 – 9, 2021
- September 15, 2021

In addition, the RSP included the collection of chlorophyll a grab samples at a single depth of approximately 1.0-m in the forebay of each development during the monthly discrete water quality sampling events. Since forebay water quality monitoring was not conducted at the Byllesby Development in 2020, chlorophyll a sampling in the Buck forebay was also delayed such that samples from both forebay monitoring locations would be collected during the same year (in 2021). Therefore, monthly chlorophyll a grab samples were collected at both the Buck forebay and Byllesby forebay monitoring locations during July, August[9], and September 2021. Results from the water quality sampling program at Byllesby and Buck (chlorophyll a sampling only) during 2021 will be provided in detail in the final study report to be included with the USR and summarized in the FLA.

Appalachian is also conducting a study to evaluate the potential impact that Project operations, in particular drag rake operations, have on turbidity concentrations in the Project tailraces. Refer to Section E.7.2.1.2 for a description of this study.

[7] Water quality and temperature data sondes were downloaded every 2 – 3 weeks with the exception of a high flow event during mid-August when the remnants from Tropical Storm Fred passed through the upper New River basin. Water quality download events resumed in late August, 2021 as Project inflows receded to typical seasonal conditions.

[8] Based on comments and recommendations from the ISR, the 2021 water quality monitoring period was to be conducted from July through September. The initial deployment and subsequent removal of water quality monitoring equipment extended the actual monitoring period from mid-June to early-October, 2021 (expected).

[9] The chlorophyll a grab samples were shipped to an off-site laboratory for analysis. The shipping provider utilized for the August samples did not deliver them to the laboratory within the required sample hold period, therefore, the samples were not analyzed. As a result, HDR collected additional chlorophyll a grab samples in early September to replace the August samples.

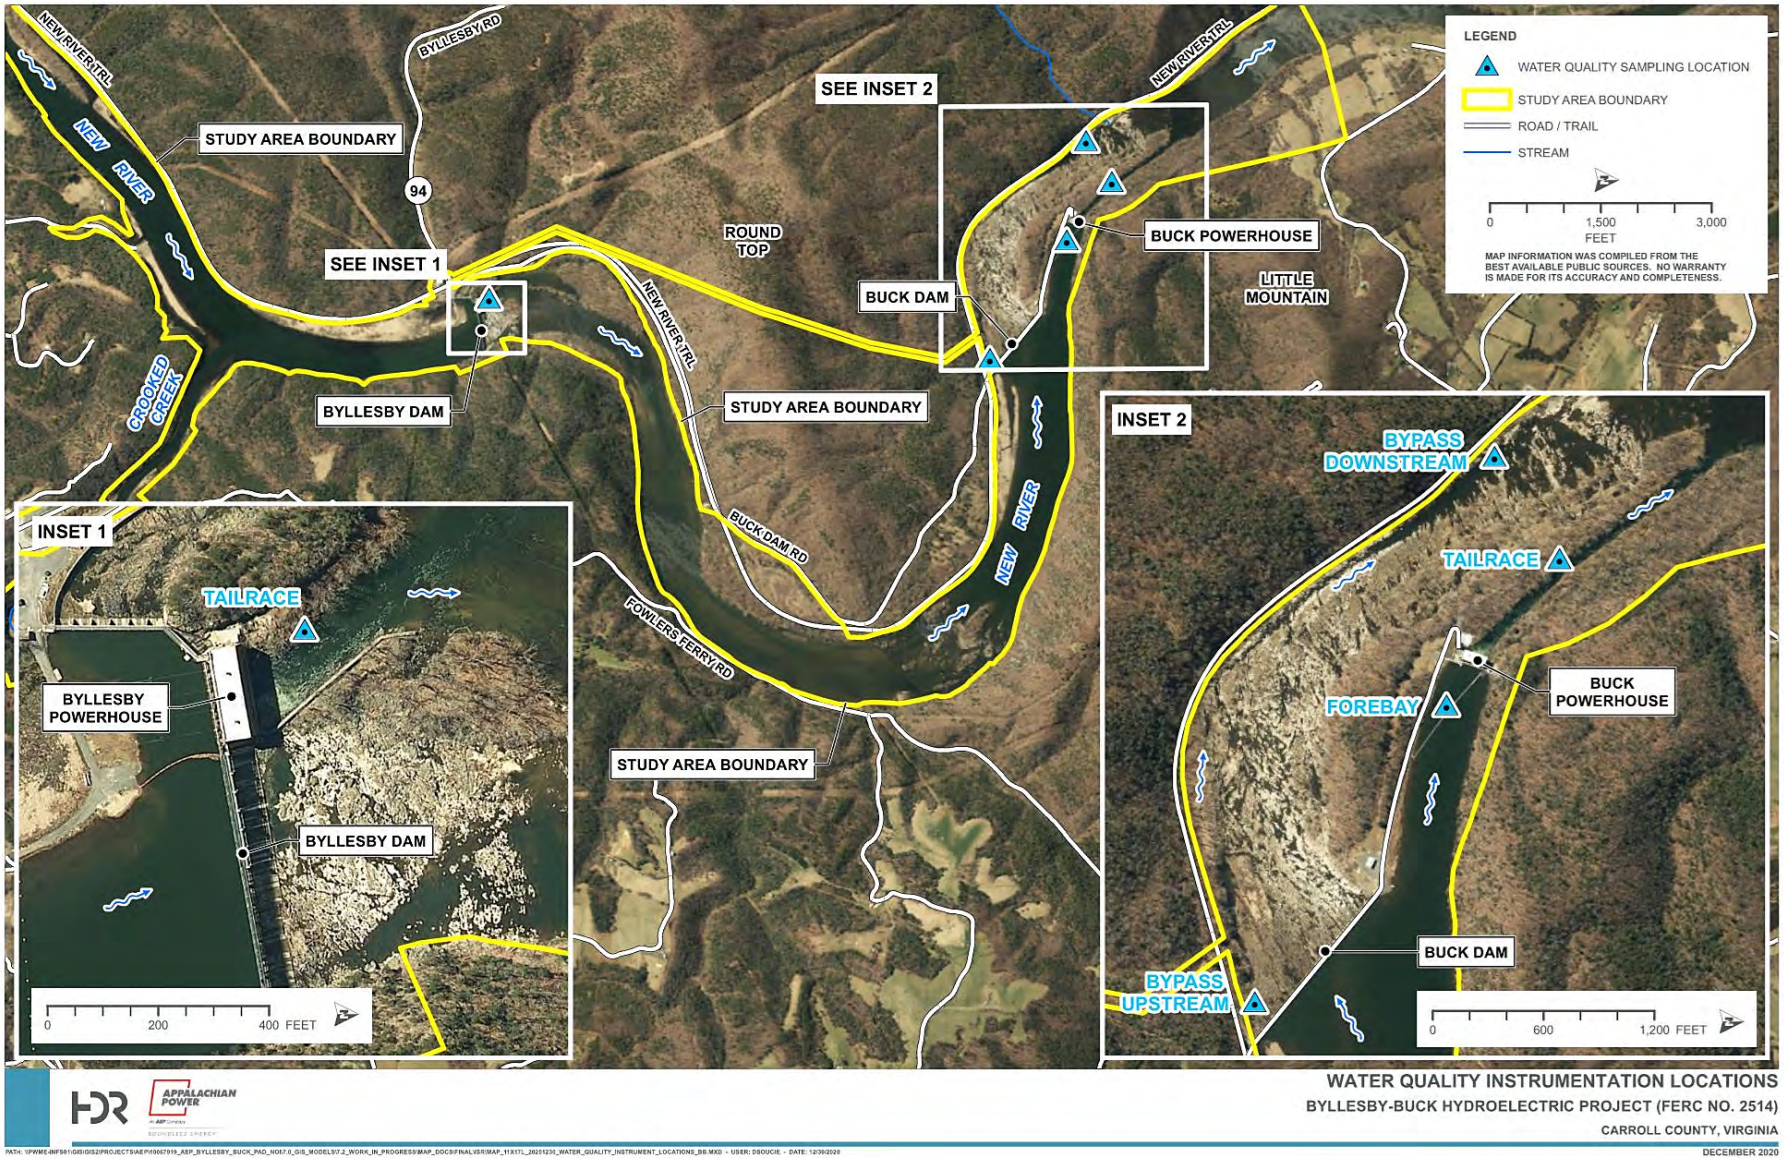

Figure E.8-3. Water Quality Study Monitoring Locations

E.8.2.2 Project Impacts on Water Resources

FERC did not identify any environmental issues related to water use/quality to be addressed in their NEPA document.

The results of the studies conducted for the previous relicensing, and results analyzed to date from the study conducted for this relicensing, support a conclusion that due to the small size and short retention time of the Project reservoirs, the lack of thermal stratification in the reservoirs, and the run-of-river operation of the Project, the Project does not affect ambient water quality (i.e., water temperature and DO levels) in this reach of the upper New River during normal project operations.

Diversion of flows for power generation does have the potential to impact water quality in the bypass reaches. Reductions of flow in the bypass reaches increases the travel time of water through the reach and also reduces the dilution of any substances introduced into the bypass reach. Reduced discharge into the bypass reaches also modifies the temperature regime immediately downstream of the dams.

Infrequent maintenance dredging has historically been conducted in the vicinity of the dam or intake at either development. Dredging has the potential to have short-term impacts on local water quality through the resuspension of sediment. Conducting all dredging operations in accordance with the terms and conditions of permits and approvals issued by USACE and VDEQ, including implementation of Best Management Practices (silt curtains, controlled return water, etc.), should maintain water quality at and downstream of the powerhouse.

Appalachian will further evaluate potential Project impacts on water quality when the ongoing Water Quality Study is completed; study methods and results will be included in the USR and summarized in the FLA.

The Licensee does not anticipate that operation and maintenance of the Project over the new license term will have any short- or long-term, unavoidable, adverse impacts on water quality and use.

E.8.3 Protection, Mitigation, and Enhancement Measures Proposed by the Applicant, Resource Agencies, and/or Other Consulting Parties

Water quality in the streams flowing into the Project, tailrace, and bypass reach is consistent with applicable Virginia state water quality standards for temperature, DO, and pH for Class IV New River surface waters. While there is no state standard for specific conductivity, concentrations were above 150 µS/cm and less than 500 µS/cm, which is generally considered to be suitable for most fish (USEPA 2012).

Because (1) normal Project operations have not shown in the relicensing studies or historical data to be impacting water quality in the New River downstream of the Project, (2) water quality in the upper New River upstream and downstream is periodically monitored by state agencies, and (3) out of recognition of the intensive effort, cost, and equipment challenges associated with collection of this data for the relicensing, Appalachian does not propose and does not believe it is necessary to conduct long-term or periodic water quality monitoring to address potential impacts of normal Project operations over the term of the new license.

Appalachian proposes to continue the existing run-of-river operations for the protection of water quality and fish and wildlife resources. Appalachian recognizes the potential for minimum flows to the bypass reach to affect local water quality, particularly during high air temperature, low-flow periods. Because the Water Quality and Bypass Reach Flow and Aquatic Habitat studies are still on-going, Appalachian will provide further details and evaluation in the USR and FLA.

E.9 Fish and Aquatic Resources

E.9.1 Affected Environment

E.9.1.1 Aquatic Habitat

E.9.1.1.1 Impoundments

The Project consists of two reservoirs surrounded primarily by a dense forest, with few natural wetland areas due to the relatively high topographic relief. The reservoir formed by the Byllesby Dam is approximately 16.8 miles long with a surface area of 239 acres at EL. 2079.2. The reservoir is characterized by shallow shorelines that drop off steeply, converging toward the center of the channel, with vegetated floodplains on the left descending bank and steep rock facing on the right descending bank. The reservoir is generally sparse in woody debris and submerged aquatic vegetation. Substrates within the reservoir are predominantly sand (70%), silt (20%), gravel (5%), and boulder (5%). Recent water quality data collected during relicensing studies (see Section E.8) indicated that water quality parameters (temperature, pH, DO, and conductivity) met state water quality criteria and remained relatively consistent throughout the Byllesby reservoir. Diverse fish and benthic macroinvertebrate habitats exist in the deep impounded reach above Byllesby Dam as well as in shallower, swift-moving areas at the upper end of the impoundment.

The reservoir formed by the Buck Dam is approximately 5.8 miles long with a surface area of 66 acres at EL. 2,003.4 ft. The Buck reservoir is also characterized by shallow shorelines that drop off steeply, converging toward the center of the channel, with vegetated floodplains on the left descending bank and steep rock facing on the right descending bank. The reservoir is generally sparse in woody debris and submerged aquatic vegetation. Substrates within the reservoir are predominantly sand (60%), silt (20%), gravel (15%), and boulder (5%). The upper end of the impoundment, corresponding to the Byllesby bypass channel and tailrace, is relatively shallow with consistent water depths across the width of the channel. Water quality data collected during relicensing studies (see Section E.8) indicated that water quality parameters (temperature, pH, DO, and conductivity) met state water quality criteria and remained relatively consistent through the Buck reservoir, with exception of DO and velocities, which were much higher in the upper reach of the impoundment compared to the downstream, deeper section of the reservoir. These areas of the impoundment also provide a diversity of fish and benthic macroinvertebrate habitats.

E.9.1.1.2 Bypass Reaches

The Byllesby Development includes a short, 475-ft-long bypass reach consisting primarily of exposed bedrock and rock outcroppings. The depth of the channel is fairly uniform downstream of the spillway,

and remains shallow and swift until converging with the tailrace channel further downstream. The Buck Development includes a 4,100-ft-long, steep bypass reach consisting primarily of exposed bedrock. The upper portion of the reach exhibits long vertical slabs of bedrock running parallel to river flow, preventing the accumulation of smaller particle substrates in the upper reach of the channel. The channel curves about midway down the bypass channel, so that the long vertical slabs of bedrock are positioned perpendicular to the stream flow and facilitating the accumulation of smaller substrates on the downstream side of the bedrock slabs. As such, the lower half of the Buck bypass reach generally contains a larger quantity and diversity of microhabitats for colonization and utilization by fish and benthic macroinvertebrates.

Availability of aquatic habitat in the bypass reach under varying flows is being evaluated by Appalachian for the Bypass Reach Flow and Aquatic Habitat Study, which is ongoing. This section will be updated in the FLA to include a summary of findings from this study, which will be included in detail in the USR.

E.9.1.1.3 Tailraces

The Byllesby tailrace consists of a 300-ft-long reach defined by a bedrock outcrop (island) on the left and a concrete wall on the right. The tailrace is relatively narrow and variable in depth compared to the spillway bypass channel. The tailrace flows into two potential pathways, either toward the left side of an island near the left descending bank (characterized by swift riffle and run habitats) or to the right toward and converging with the spillway bypass reach downstream of the island.

The Buck tailrace consists of a channel that is approximately 1,700 ft long and 70 ft wide. The depth of the channel is fairly uniform downstream of the immediate vicinity of the powerhouse, averaging 6.5 to 10 ft at a point 160 ft downstream of the powerhouse. This narrow, shallow tailrace results in relatively higjh water velocities in the tailrace which likely restricts its use as aquatic habitat to large-bodied fishes like Walleye (*Sander vitreus*).

This section will be updated in the FLA to include a summary of relevant findings from Bypass Reach Flow and Aquatic Habitat Study, which will be included in detail in the USR.

E.9.1.1.4 Essential Fish Habitat

Based on a review of the NMFS online database, no EFH, as defined under the Magnuson-Stevens Fishery Conservation and Management Act or established by the NMFS has been identified in the vicinity of Project.

E.9.1.2 Resident Fish Community

The New River contains a variety of popular sportfish species such as Smallmouth Bass (*Micropterus dolomieu)*, Spotted Bass (*Micropterus punctulatus*), Largemouth Bass (*Micropterus salmoides*), Rock Bass (*Ambloplites rupestris*), Striped Bass (*Morone saxatilis*), hybrid bass (Striped Bass x White Bass hybrid), Muskellunge (Esox masquinongy), Walleye, Black Crappie (*Pomoxis nigromaculatus*), Channel Catfish (*Ictalurus punctatus*), Flathead Catfish (*Pylodictis olivaris*), Redbreast Sunfish (*Lepomis auritus*), and Bluegill (*Lepomis macrochirus*).[10] Trophy Smallmouth Bass and Channel Catfish are known to occur between the Fries and Byllesby dams. Channel Catfish are often sought near the base of the Byllesby Dam, while Smallmouth Bass, Spotted Bass, and Walleye are found throughout the entire reach (VDGIF 2017a). State record Walleye have been caught near Buck Dam, and deep pools downstream of the dam have yielded trophy-size catfish and Muskellunge (VDGIF 2017a).

The New River is home to 44 native fish species and at least 57 introduced fish species (Carey et al. 2017). However, the number of endemic species[11] in the New River (8 species) is high in comparison to other eastern U.S. rivers; and has been attributed to the immobility of species. According to Orth (2017), the New River has a relatively high number of endemic species due to the immobility of species and natural barriers, which geographically isolated fishes during the Pleistocene. The eight endemic fishes include three minnows, two sculpins, and three darters, as follows: Bigmouth Chub (*Nocomis platyrhynchus*), Kanawha Minnow (*Phenacobius teretulus*), New River Shiner (*Notropis scabriceps*), Kanawha Sculpin (*Cottus kanawhae),* Bluestone Sculpin (*Cottus sp.),* Candy Darter (*Etheostoma osburni),* Kanawha Darter *(Etheostoma kanawhae),* and Appalachian Darter *(Percina gymnocephala)* (Orth 2017).

The Bigmouth Chub and Kanawha Minnow both prefer habitats of clear, rocky streams and rivers (Jenkins and Burkhead 1983). The New River Shiner inhabits cool, clear tributaries and the upper main channel of the New River. The Kanawha Sculpin is found in rocky areas of limestone streams and cave streams (Encyclopedia of Life 2017). The Bluestone Sculpin, Candy Darter, and Kanawha Darter all prefer swift riffles over gravel or rubble (Jenkins and Burkhead 1983; NRCS, n.d.; NatureServe. 2013).

[10] In accordance with the "Common and Scientific Names of Fishes from the United States, Canada, and Mexico" (American Fisheries Society Special Publication 34; 2013), throughout this document, common names of fishes are capitalized.

[11] **A** species that is uniquely found in one part of the world, in geographically localized area only.

The Candy Darter is an endemic fish in the New River drainage basin. The Candy Darter prefers rock, rubble, or gravel riffles in creeks or small to medium rivers (Rohde et al. 1996). Five watersheds that contain known Candy Darter habitats are listed as critical habitat; all five watersheds are tributaries to the New River. The nearest critical habitat to the Project is the Cripple Creek tributary, which confluences with the New River 5 river miles downstream of Buck Dam.

E.9.1.2.1 Previous Fishery Surveys and Assessments

1990 Byllesby-Buck Project Survey

In 1990, a fishery survey was conducted by Appalachian in the Project area as part of the previous relicensing of the Byllesby-Buck Project. Water quality, physical, hydrological, and operational data were collected and analyzed as part of the field data collection. The study consisted of six sampling events per month between May and October 1990 utilizing gill nets, hoop nets, and electrofishing (Appalachian 1991b). Adult and juvenile fish were sampled as follows:

- Electrofishing was performed at two stations within reaches upstream of the Byllesby reservoir, between the two dams, and downstream of Buck Dam.
- Electrofishing and hoop netting were performed at two stations each in the upper, middle, and lower portions of the Byllesby and Buck reservoirs.
- Gill netting was performed at two stations each in the upper, middle, and lower portions of the Byllesby reservoir.

A total of 2,679 fish and 34 distinct species were collected (Appalachian 1991b). A complete list of species collected during this study is provided in Table E.9-1.

Table E.9-1. Fish Community Documented near the Project in 1990 (Appalachian 1991b)[1]

Family	Common Name	Scientific Name	Number	Percent composition
Catostomidae	Northern Hogsucker	*Hypentelium nigricans*	96	3.6
	Redhorse	*Moxostoma* sp.	1	0.0
	Silver Redhorse	*Moxostoma anisurum*	1	0.0
	White Sucker	*Catostomus commersonii*	26	1.0
Centrarchidae	Black Crappie	*Pomoxis nigromaculatus*	3	0.1
	Bluegill	*Lepomis macrochirus*	35	1.3
	Hybrid Sunfish	*Lepomis* hybrid	3	0.1
	Largemouth Bass	*Micropterus salmoides*	2	0.1
	Pumpkinseed	*Lepomis gibbosus*	5	0.2
	Redbreast Sunfish	*Lepomis auritus*	237	8.8
	Rock Bass	*Ambloplites rupestris*	352	13.1

Family	Common Name	Scientific Name	Number	Percent composition
	Smallmouth Bass	*Micropterus dolomieu*	606	22.6
	Spotted Bass	*Micropterus punctulatus*	460	17.2
Cottidae	Sculpin	*Cottus* spp.	2	0.1
Cyprinidae	Bigmouth Chub	*Nocomis platyrhynchus*	14	0.5
	Bluehead Chub	*Nocomis leptocephalus*	16	0.6
	Bluntnose Minnow	*Pimephales notatus*	23	0.9
	Central Stoneroller	*Campostoma anomalum*	1	0.0
	Common Carp	*Cyprinus carpio*	76	2.8
	Golden Shiner	*Notemigonus crysoleucas*	11	0.4
	Mimic Shiner	*Notropis volucellus*	17	0.6
	New River Shiner	*Notropis scabriceps*	23	0.9
	Rosyface Shiner	*Notropis rubellus*	167	6.2
	Shiner	*Notropis* spp.	9	0.3
	Silver Shiner	*Notropis photogenis*	7	0.3
	Spotfin Shiner	*Cyprinella spiloptera*	123	4.6
	Spottail Shiner	*Notropis hudsonius*	20	0.7
	White Shiner	*Luxilus albeolus*	29	1.1
Esocidae	Muskellunge	*Esox masquinongy*	7	0.3
Ictaluridae	Channel Catfish	*Ictalurus punctatus*	141	5.3

Percidae	Appalachia Darter	*Percina gymnocephala*	5	0.2
	Greenside Darter	*Etheostoma blennioides*	5	0.2
	Johnny Darter	*Etheostoma nigrum*	6	0.2
	Common Logperch	*Percina caprodes*	71	2.7
	Sharpnose Darter	*Percina oxyrhynchus*	1	0.0
	Yellow Perch	*Perca flavescens*	1	0.0
		Total	2,679	-
		Number of Species	34*	-

[1] This list was compared with the undated species list provided by the VDWR for the entire New River; these species represent approximately 55 percent of the species diversity of the comprehensive list from the entire New River.
* *Lepomis* spp., *Moxostoma* sp., and *Notropis* spp. were not counted as distinct taxa, as additional individuals from these genera were collected and identified to the species level.

Smallmouth and Spotted basses were the most abundant fish collected in the 1990 study; however, Rock Bass, Redbreast Sunfish, Rosyface Shiner (*Notropis rubellus*), Channel Catfish, Spotfin Shiner (*Cyprinella spilopterus*), and Northern Hogsucker (Hypentelium nigricans) were also abundant. In comparing the three riffle/run sites (upstream of the Byllesby Development, between the

developments, and downstream of the Buck Development), species catch per unit effort (CPUE) was highest at the site downstream of Buck Dam, while catch rates were fairly even between the other two riffle/run sites. The authors of the study report noted that this result may be attributable to the isolation of the two upstream sites by the Project dams and the upstream Fries Dam, limiting fish movement into this portion of the river (Appalachian 1991b).

1997 Survey Below Buck Dam

In 1997, Appalachian assessed the effectiveness of the ramping procedures for the Buck Dam spillway gate operations for the protection of fish communities in the bypass reach. Backpack electrofishing samples were collected from representative pools in the bypass reach following the cessation of spillway releases of flows in the range of 4,300 cfs to 6,140 cfs, which resulted in the collection of 734 fish representing 24 species. The final report on this assessment was filed with FERC by Appalachian on September 12, 1997 (Appalachian 1997).

The study report noted that there was much more flowing-water habitat (riffles/runs) in the area immediately downstream of the spillway compared to a greater number of isolated pools farther downstream, which contributed to the differences observed in the spatial distribution of the fish community. For example, Central Stoneroller (*Campostoma anomalum*), White Shiner (*Luxilus albeolus*), White Sucker (*Catostomus commersonii*), Northern Hogsucker, darters, and Walleye were collected more frequently in the riffle/run habitats within about 1,600 ft downstream of the spillway compared to collections from the downstream isolated pools, where species such as Rock Bass, Redbreast Sunfish, Green Sunfish (*Lepomis cyanellus),* and Bluegill were collected in greater numbers. Further, fourteen species collected during the 1990 fish surveys (Appalachian 1991b), primarily from impoundments, were not collected in the 1997 survey below Buck Dam (Appalachian 1997).

2016-2017 Fries Hydroelectric Project Survey (Upstream of Project)

The Fries Project is located approximately 8.6 river miles upstream of the Byllesby Dam. In association with the relicensing of the Fries Project, fish sampling was performed utilizing a variety of methods and gear types (i.e., backpack, raft, and boat electrofishing; snorkel surveys; cast netting; angling; night observations; set lines; gill netting; and minnow traps) from July to October 2016, and May to July 2017. Five study reaches were established within the Fries Project, including reference reaches upstream and downstream of the dam, the impoundment, the bypass, and the tailwaters (Table E.9-2) (Carey et al. 2017).

Table E.9-2. Summary of Study Reach Descriptions (Carey et al. 2017)

Reach	Location and Length	Description
1	Upstream Reference Reach (400 m)	The widest part of the river with heterogenous habitats, flows, and substrates; some submerged aquatic vegetation present
2	Impoundment (2,300 m)	Within 1.4 river miles of the dam structure; characterized by sediment accumulations with sand substrate; some boulders and bedrock present; submerged aquatic vegetation growth in the lower half of the reach
3	Bypass (150 m)	Approximately 150 m downstream of the dam structure; characterized by a scoured streambed with boulders or bedrock; little or no flow; some silt and algae present along the left descending bank
4	Tailwater (800 m)	Just below the powerhouse; mostly non-wadeable, slow pools and glides with bedrock, boulder, sand, and silt substrates; transitional area in downstream end containing greater habitat diversity
5	Downstream Reference Reach Mainstem (400 m)	Riffles, runs, and glides with gravel and sand substrates
	Downstream Reference Reach Side Channel (500 m)	Channel flowing along an island; characterized by slow-moderate flowing glides, riffles, and runs with sand, gravel, and cobble substrates and large woody debris present.

The study found 43 fish species across all five study reaches using multiple sampling techniques (Carey et al. 2017). Native and endemic species combined for 57 percent of the total number of fish collected, with the remaining 43 percent consisting of introduced species. A list of fish species documented in this study is provided in Table E.9-3.

Table E.9-3. Fish Community Documented near the Fries Project in 2016 (Carey et al. 2017)

Common Name	Scientific Name	Native/Endemic/Introduced

Common Name	Scientific Name	Native/Endemic/Introduced
Walleye	*Sander vitreus*	N
Yellow Perch	*Perca flavescens*	I

Species richness (number of distinct taxa) was greatest in Reach 4 (Tailwater; refer to Table E.9-2 for reach descriptions and Table E.9-4 for study results), and lowest in the Main Channel of Reach 5 which contained the greatest percentage of native and endemic species followed by the Tailwater (Reach 4) and the Upstream Reference Reach (Reach 1). The increasing habitat complexity at the transition zone between Reach 4 and Reach 5 likely contributed to Reach 4 having the greatest species richness. Reaches 2 (Impoundment) and 3 (Bypass) contained the highest percentage of introduced species at 57 and 53 percent, respectively. Many of the introduced species consist of sportfish, such as Rock Bass and Redbreast Sunfish, which were commonly collected throughout the study. Bigmouth Chub was the most dominant species collected in both reference reaches (which contained a greater amount of the riffle-run habitat preferred by this species) and was absent from the Impoundment (Reach 2). The impoundment exhibited a different fish community as compared to the other study reaches, with higher collections of White Sucker, Common Carp (*Cyprinus carpio*), Largemouth Bass, Bluegill, Channel Catfish, and Black Crappie, as well as the only instances of Gizzard Shad (*Dorosoma cepedianum*) and Golden Shiner (*Notemigonus crysoleucas*), both characterized as pelagic species. Notably, the Appalachia Darter was collected both above and below Fries dam, however the Kanawha Minnow was only collected downstream of the dam.

Given that the Fries Project is in close proximity to the Byllesby Dam (approximately 8.6 river miles upstream), it would be expected that similar fish species are found within the Byllesby-Buck Project where habitat characteristics are similar to the study reaches.

Table E.9-4. Fries Project Survey Results by Study Reach (Carey et al. 2017)

Reach	Location	No. Species Collected	No. of Species [Percent Total]		
			Native	Endemic	Introduced
1	Upstream Reference Reach	17	9 [53%]	2 [12%]	6 [35%]
2	Impoundment	23	9 [39%]	1 [4%]	13 [57%]
3	Bypass	19	8 [42%]	1 [5%]	10 [53%]
4	Tailwater	30	16 [53%]	4 [13%]	10 [33%]
5	Downstream Reference Reach Mainstem	11	8 [53%]	3 [20%]	4 [27%]
	Downstream Reference Reach Side Channel	16	13 [62%]	3 [14%]	5 [24%]

Surveys and Assessments by VDWR

Fish surveys were conducted (VDGIF 2015) on the upper New River from 2004 to 2014. In spring 2014, electrofishing samples were collected at twelve sites from Allisonia in Pulaski County upstream to Fries Dam. Samples were dominated by Smallmouth Bass, followed by Rock Bass, Channel Catfish, Walleye, Flathead Catfish, and Redbreast Sunfish. A total of 232 adult Smallmouth Bass were collected, ranging in size from 7 to 22 inches (presumably total length, but not stated in original report). Results were used to calculated Proportional Size Distribution (PSD) scores for select sportfish species.

The PSD is a simple measure that summarizes the size structure of a fish population by categorizing each species by specific length classes (Gabelhouse 1984): stock (S), quality (Q), preferred (P), memorable (M), and trophy (T) lengths. Stock-length fish are generally defined as the age at which the fish enters the fishery, i.e., when it becomes vulnerable to gear and/or reproductively active, and when it becomes recreationally valuable (the minimum size of fish most anglers would like to catch). The most common metric used for PSD values is quality length (or PSD-Q), where PSD equals the number of fish greater than quality length, divided by the number of fish at stock length, multiplied by 100. PSD values range from 0 to 100. A low PSD value indicates there are very few large fish in the population, whereas a large PSD value indicates few small fish in the population. An ideal or balanced fish population should consist of a range of size structures and have predator species with a PSD range of 40-70 and prey species with a PSD range of 20-60 (Murphy and Willis 1996).

In 2014, the Smallmouth Bass PSD-Q downstream from Fries Dam was 45, indicating that 45 percent of Smallmouth Bass collected were of quality length (11 inches) or larger, and within the 40 to 60 range is considered (VDGIF 2015) representative of a healthy river Smallmouth Bass population. The remainder of the 2014 data indicated PSD-P was 28, PSD-M was 17, and PSD-T was 4. The average relative weight of Smallmouth Bass was 90, indicating that Smallmouth Bass in this section of the New River are healthy. Flathead and Channel catfish showed evidence of excellent reproduction in sampling, but no additional information was provided for these fish.

Rock Bass collected in 2014 ranged in size from 3 to 9 inches with an average size of 6 inches (VDGIF 2015). The Rock Bass PSD-Q was 27, which falls within the ideal PSD range for a prey species. Walleye length ranged in size from 13 to 29 inches, with an average of 17 inches. The Walleye PSD-Q was 95, well above the 30-60 range identified by Murphy and Willis (1996) as indicative of a balanced community, indicating that a large portion of the Walleye population is greater than or equal to quality length (15 inches). This may suggest limited recruitment (fewer younger fish) or gear bias

(Gouffaux et al. 2005). However, with a relative weight of 84, the Walleye population appears to be in moderately healthy condition (VDGIF 2015).

E.9.1.2.2 Temporal and Spatial Distribution of Fish Communities

No obligate long-run anadromous or migrant fish species (catadromous or anadromous) exist in the Project area, as movement of fish is currently limited by dams upstream and downstream of the Project. However, some species may exhibit local spawning migrations, such as Walleye or Muskellunge (Younk et al. 1996; Hayden et al. 2014). Although the movement of these species is largely precluded by the dams, the areas upstream and downstream remain a high-quality fishery.

Fish passage is not provided at any of the existing New River dams and there are currently no plans on record to install fish passage at any other dam on the New River.

E.9.1.2.3 Spawning Run Timing and Extent and Location of Spawning, Rearing, Feeding, and Wintering Habitats

As stated previously, the upper New River supports a cool-water fishery and is a popular fishing area for a variety of sportfish. Based on information provided by VDWR (VDGIF 2017a), the Project area is specifically known for the quality of Smallmouth Bass, Channel Catfish, Spotted Bass, Walleye, and Muskellunge fishing opportunities. These species exhibit a range of seasonal behaviors related to the timing of spawning activity, and the location of spawning, rearing, feeding, and wintering habitats. The life-history characteristics of these species are described below. Threatened or endangered fish or aquatic species are discussed separately in Section E.9.1.5.

Spawning characteristics of fish species likely to use the Project waters (VDGIF 2017c), as well as the fishery study conducted by Appalachian for the previous relicensing effort (Appalachian 1991b) are summarized below. These studies concluded that <1 to 13 percent of available spawning habitat within the Project area is potentially exposed under natural riverine conditions. Refer to Table 13 in Appalachian (1991b) for a listing of spawning characteristics of fish species in the Project area.

Smallmouth Bass

Smallmouth Bass are native only to the Tennessee and Big Sandy River drainages of southwest Virginia but have been introduced into, and are now abundant in, most large rivers and lakes in Virginia. Smallmouth Bass prefer slow-to-moderate currents and select areas of rocky shorelines. They are most active at temperatures between 67 degrees Fahrenheit (°F) to 72°F and are intolerant of silty, warm, polluted water (VDGIF 2017c).

Spawning usually occurs in late April to early June as temperatures exceed 60°F. Males build and guard a next constructed in sand, gravel, or rubble at a depth of two to four feet (Appalachian 1991b; VDGIF 2017c). Eggs hatch between 7 and 21 days, depending on water temperature (Smith 1985).

Spotted Bass

Spotted Bass are native to western Virginia. They are typically found in warm, slow-moving streams and stream-like or riverine arms of reservoirs. Spotted bass feed on crayfish, small fish, and larval and adult insects. They spawn in the spring when water reaches between 63°F and 68°F (Appalachian 1991b). Males sweep silt from gravel or rocky substrates on the bottom of streams and rivers to make nests near brush or logs; after hatching the males guard the eggs and fry (VDGIF 2017c).

Rock Bass

Rock Bass, although not a true bass, is part of the Centrarchidae family. The Rock Bass is native to the Mississippi River, Great Lakes, and Southern Hudson Bay drainage areas, although it has been introduced throughout the Atlantic slope drainages (Rohde et al. 2009). Rock Bass prefer pools and backwater areas of clear and cool, rock-bottomed streams, usually associated with structure such as rocks or logs. Rock Bass are generalists and when young, will feed on micro-crustaceans and aquatic insects, shifting to small fish and crayfish as adults. Males construct a circular nest in shallow water over sand for spawning, which occurs from April to June (Appalachian 1991b).

Channel Catfish

Channel Catfish are found in lakes and larger rivers with relatively clean sand, gravel, or stone substrate, over mud flats, and seldom in dense weedy areas; or in deep, slow pools of swift, clear-running streams; and are often found below dams in large reservoirs (VDGIF 2017c). Spawning occurs from late May through July when water temperatures reach the mid-70s (°F). Channel Catfish often deposit their eggs on rocky ledges, undercut banks, hollow logs, and other underwater structures (Appalachian 1991b). Males guard the nest and the eggs hatch in 7 to 10 days. The fry travel in schools, which are often herded and guarded by the male (VDGIF 2017c).

Walleye

Walleyes are native to the Tennessee and Big Sandy River drainages (VDGIF 2018a), as well as the New River drainage (Palmer et al. 2005) in Virginia. They are often found in cool water next to ledges, large rocks or logs, underwater islands, edges of large beds of aquatic vegetation, along old riverbed channels, and along reefs and bars (VDGIF 2017c).

Spawning begins as early as late February when water temperatures reach approximately 45 to 55°F

(7 to 12°C). Walleye in the New River are known to migrate upstream to spawn, but are inhibited by the Byllesby and Buck dams. However, they will also spawn in lakes over rocky or gravel shoals or clean, low-growing emergent vegetation. Walleye are broadcast spawners (i.e., do not create nests); eggs are non-adhesive and unattended after being released. Eggs free-fall onto substrate or into cracks and crevices and hatch in about two weeks (Appalachian 1991b; VDGIF 2017c).

Spawning takes place primarily at dusk or night in relatively shallow, flowing habitats comprised of rocky substrates (Paragamian 1989; Smith 1985; McMahon et al. 1984; Ellis and Giles 1965). Walleyes prefer shallow shoreline areas, shoals, riffles, and dam faces with rocky substrates and good water circulation from waves or currents. Walleye typically display diurnal staging behavior at or just adjacent to spawning sites; however, studies have reported spawning during the day and in slack water habitats (Lowie et al. 2001; Corbett and Powles 1986). Males often arrive at spawning sites before females, where multiple males may spawn with one female. This usually involves a series of courtship behaviors including lateral pushing, rolling, and rapid bursts of swimming (Ellis and Giles 1965). Eggs and milt are simultaneously broadcast over the substrate when males and females are in close proximity. Fertilized eggs likely drift downstream and settle into interstitial spaces of the streambed substrate. Studies have shown that egg survival is greatest when larger, harder substrates such as boulders, rubble, and gravel dominate (Smith 1985; Johnson 1961). Hatching time varies depending on water temperature, and newly hatched fry may drift further downstream to lentic habitats and continue first-year development there (Corbett and Powles 1986; McMahon et al. 1984; Olson et al. 1978). Male Walleye usually mature at ages two to three (300–340 millimeters) and females at ages four to five (430 millimeters) (Smith 1985).

Muskellunge

Muskellunge are not believed to be native to Virginia, but have been introduced to the New River, as well as other drainages. Muskellunge prefer cool, clear lakes with abundant vegetation or long pool areas of rivers near fallen debris and other submerged structures. They spawn in early spring. Eggs are fertilized and discharged over muck or marl bottoms with aquatic vegetation in shallow bays and coves of lakes, or in eddies upstream or downstream of riffles. In Virginia, most Muskellunge populations are maintained through stocking (Appalachian 1991b).

E.9.1.2.4 Management Activities by VDGIF

Based on available stocking records, the VDWR stocks two species of management interest in the New River, Walleye and Muskellunge (VDGIF 2014). Stocking information for each of these species is summarized below.

Walleye

A two-year radio-telemetry study of the Walleye population of Claytor Lake and the upper New River found that two genetically distinct populations coexist within the New River system. One population originates from Walleye fingerlings obtained from outside of the New River drainage (i.e., not native to the New River), while the other is an indigenous population unique to the upper New River. The Claytor Lake Walleye generally spawn at the first riffle area above the reservoir, while those living in the New River spawn at two riffle areas well upstream of Claytor Lake (Palmer et al. 2005).

Since 2000, Walleye have been stocked and managed from Fries Dam downstream to Claytor Lake Dam in an effort to restore the fishery to a self-sustaining population level (VDGIF 2013). According to Palmer et al. (2005), the coexistence of the two distinct populations of Walleye within the upper New River and Claytor Lake may warrant different management strategies and suggested that management focus efforts on encouraging the exploitation of the Claytor Lake stock to reduce the nonindigenous population. To support the conservation of the indigenous population in the upper New River, Palmer et al. (2005) recommended the implementation of strict harvest regulations and the exclusive use of indigenous Walleye fingerlings (offspring from upstream spawning sites) as they may be better adapted to the New River environment and may exhibit higher recruitment to the fishery than the nonindigenous stocks. Since 2003, over one million indigenous Walleye from upstream spawning sites have been stocked in the New River between Allisonia, in Pulaski County, upstream to Fields Dam, near the community of Mouth of Wilson, in Grayson County (VDGIF 2017a) (Figure E.9-1).

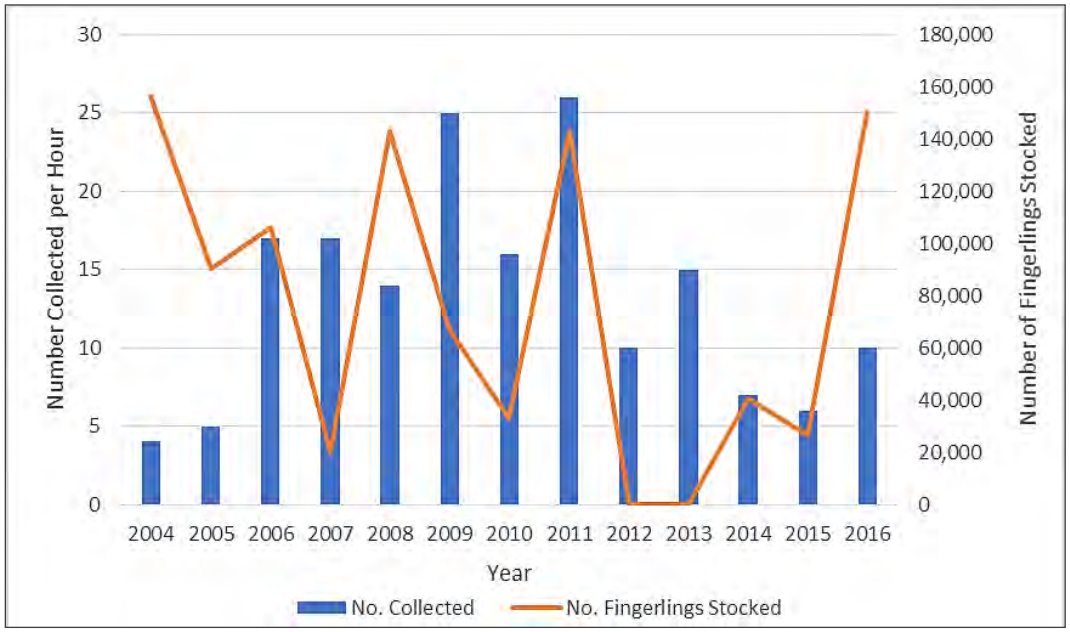

Figure E.9-1. Walleye Catch Per Hour and Annual Stocking Rates from the Upper New River – Allisonia Upstream to Fries Dam, 2004-2016 (VDGIF 2017b)

Based on recent surveys performed by VDWR, the largest numbers of Walleye were collected from 2006 to 2011, following years of consistently high stocking rates (an average of almost 95,000 fingerlings per year from 2004 to 2011). However, no Walleye were stocked between 2012 and 2013 as part of an evaluation of the need for continued stocking. A decline in Walleye was reflected in spring electrofishing catch rates, and the collection of limited numbers of naturally reproducing Walleye indicated the necessity of continued stocking to maintain a viable recreational fishery.

A recent upper New River Walleye Management Plan developed by the VDWR (VDGIF 2017b) outlines several objectives with the goal of maintaining the genetically unique, naturally reproducing upper New River Walleye stock. These objectives include: (1) maintaining an average spring electrofishing catch rate between 15 and 25 Walleye per hour; (2) sustaining angler catch rates of adult Walleye at one fish per four hours of fishing between February and April; (3) maintaining New River Walleye stock through allele frequency monitoring; and (4) increasing the Walleye spawning stock to adequate levels for natural reproduction in support of a viable recreational fishery. With these objectives, VDWR annually collects adult Walleye to use as brood stock in order to maintain the genetic structure of the population. Annual electrofishing surveys and allele frequency monitoring are conducted, as well as creel surveys and review of management strategies. Creel and slot limits are managed by river reach so that certain populations are protected for spawning and/or during spawning seasons.

Muskellunge

Since the 1970s, Muskellunge have also been stocked in the New River with the goal of establishing a reproducing, self-sustaining population. Muskellunge are managed primarily as a trophy fish and secondarily as a predator for forage fish control. In the New River, Muskellunge exhibit fast growth rates and regularly reach trophy sizes, suggesting that the conditions of the New River are well-suited to support this species. Management is implemented by minimum length and creel limit regulations. As with other Virginia Rivers, Muskellunge are stocked to the New River on a rotating priority system, where waterbodies not stocked the previous year are given higher priority than those that were stocked (Brenden 2005). According to the latest (available) warmwater fish production and stocking information 500 nine-inch-long Muskellunge were stocked in the upper New River in Wythe and Carroll Counties in 2014 (VDGIF 2014). However, as of 2014, in response to an increase in the population and evidence of natural production, Muskellunge stockings were discontinued in the New River downstream of Claytor Dam in 2011 (Copeland 2014) and upstream of Claytor Dam in 2018 (VDGIF 2019).

E.9.1.3 Benthic Aquatic Community

E.9.1.3.1 Macroinvertebrates

Benthic macroinvertebrates and crustaceans such as crayfish are an important component of riverine systems where they serve as a food resource for fish and as useful indicators of water quality and environmental stressors. Often, the presence of pollution-intolerant macroinvertebrates, or EPT taxa (Ephemeroptera [mayflies], Plecoptera [stoneflies], and Trichoptera [caddisflies]) can be indicative of a healthy stream.

No recent historical macroinvertebrate data is available from within the Project Boundary. However, during the 2016-2017 aquatic resource surveys conducted at the Fries Project, 17 species of Odonata representing 4 families were collected from Reaches 1, 2, 4, and 5; none were collected from Reach 3 (Carey et al. 2017). The pygmy snaketail (*Ophiogomphus howei*) was collected in Reaches 4 and 5. Additionally, the Allegheny river cruiser (*Macromia alleghanensis*), spine-crowned clubtail (*Gomphus abbreviates*) and green-faced clubtail (*G. viridifrons*) were also collected in the surveys.

Specific to the Project, the VDCR, in a letter from dated September 23, 2017, identified two species of aquatic insect as “species of greatest conservation need (SGCN)” with the potential to occur within the Project vicinity: the mustached clubtail (*Gomphus adelphus*) and the pygmy snaketail. Additional information regarding these rare species is provided in Section E.9.1.5.

E.9.1.3.2 Crustaceans

Crayfish function as an important prey item for sportfish species in the New River. In comments filed on the PAD for the Fries Project, Orth (2015) noted that a number of species of New River crayfishes live amongst the gravel and cobble substrates (Roell and Orth 1992, as cited by Orth [2015]). Many of the large-bodied fishes (Smallmouth Bass, Rock Bass, Flathead Catfish, Walleye) in the New River are highly dependent on crayfish as an energy source (Roell and Orth 1993, as cited by Orth [2015]) and these crayfish can support local bait harvest, when locally abundant (Nielsen and Orth 1988, as cited by Orth [2015]).

A 2008 crayfish survey in the New River for the Claytor Project relicensing effort collected 690 crayfish, representing three species, at multiple sites downriver from the Claytor Lake Dam. The three crayfish taxa included the invasive Northern Virile Crayfish (*Orconectes virilis*), Spiny Stream Crayfish

(*Orconectes cristavarius*), and the New River Riffle Crayfish (*Cambarus chasmodactylus*)[12]. The invasive Northern Virile Crayfish dominated overall crayfish densities (DTA 2008).

As part of the recent Fries Project relicensing studies, crayfish surveys were completed using a variety of sampling gear and methodologies (e.g., kick-net, seine-haul, D-frame dip nets, and snorkel surveys) (Carey et al. 2017). Over 800 live Spiny Stream Crayfish were collected within the study reaches upstream and downstream of the Fries Project (Reaches 1, 3, 4, and 5), but not within the Fries Project reservoir or bypass reach (Reaches 2 and 3). The Spiny Stream Crayfish was the only taxon of crayfish collected in the New River during the surveys. Based on the absence of suitable crayfish habitat (i.e., gravel and cobble substrates) in the Byllesby and Buck bypass reaches, Appalachian does not expect crayfish to be present in these reaches.

E.9.1.3.3 Freshwater Mussels

Existing relevant and reasonably available information regarding the mussel community in the Project vicinity was summarized in Section 5.4.5 of the PAD (Appalachian 2019). Eleven species of freshwater mussels have been documented in the upper New River in recent surveys of the upper New River (Pinder et al. 2002; Alderman 2008; Stantec 2016, 2017a, 2018a, 2018b).

Pinder et al. (2002) conducted a drainage-wide survey to determine the status and distribution of freshwater mussels in the New River in Virginia. Mussels were sampled at 134 sites, which included the mainstem and tributaries in the New River Basin between 1997 and 1998. Sampling was conducted in summer and early fall during low-flow, clear-stream conditions. Sites were sampled using snorkel or viewscope survey methods. Sample transect lengths were 500 m on the mainstem and 250 m on most tributary sections. Fifty of the 134 sites yielded mussels for a total of 1,181 individuals representing eight species (Table E.9-5). The two most widely distributed species were the purple wartyback (*Cyclonaias tuberculata*) and spike (*Eurynia dilatata*).

A 2007-2008 survey by Alderman (2008) identified six extant mussel species in Claytor Lake: giant floater (*Pyganodon grandis*), paper pondshell (*Utterbackia imbecillis*), purple wartyback, pistolgrip (*Tritogonia verrucosa*), pocketbook (*Lampsilis ovata*), and spike. In 2008, two of 16 sites surveyed in the New River located downstream of Buck Dam (Buck Downsteam 1 and Buck Downstream 2) produced a total of 125 pistolgrip, 134 purple wartyback, nine pocketbook, and seven spike mussels

[12] The New River crayfish is currently under federal review for listing under the Endangered Species Act (76 FR 59835).

(Alderman 2008) (Table E.9-5). Alderman (2008) did not report length data for any of the specimens collected at these sites.

In October 2015, Stantec (2016) performed a mussel survey on the New River in Virginia, using a combination of transect and quadrat sampling either by scuba diving or snorkeling. Two of the seven sample sites (Buck Downsteam 1 and Buck Downstream 2) were located less than a mile downstream of Buck Dam and were previously surveyed by Alderman (2008). After transects were surveyed, the areas with the highest abundance of mussels were determined and selected for quantitative sampling. A total of 130 live mussels were observed in the New River during the survey. The purple wartyback was the most abundant species with 96 individuals documented, followed by the pistolgrip with 26 mussels documented (Table E.9-5). Recruitment was observed for these two species as measured lengths indicated multiple-year classes were present.

Stantec (2017a) reassessed the mussel assemblage at sites along the New River in June 2017 to document reproductive behaviors, and in September 2017 to document abundance and population dynamics. A total of 129 live mussels were collected (Table E.9-5) from two sites sampled in June, with reproductive status assessed on 59 of those, none of which were observed to brood glochidia and divers did not observe any displaying females. Seven sites were surveyed in September 2017; three upstream of Claytor dam and four downstream (Stantec 2017b). A total of four species and 337 live freshwater mussels were collected during the survey, with the majority (307 mussels) collected at sites upstream of Claytor Lake. Nearly 25 percent of the mussels collected in the survey were collected at a site located less than a mile downstream of Buck Dam where 49 purple wartyback, 3 spike, and 30 pistolgrip were collected (Table E.9-5).

Appalachian consulted with USFWS and VDWR regarding freshwater mussels at the Byllesby-Buck Project in 2016 in support of the non-capacity amendment application for the installation of the inflatable Obermeyer crest gates. In correspondence to Appalachian, dated November 15, 2016, USFWS stated that green floater (*Lasmigona subviridis*) may be present in the Byllesby-Buck Project reservoirs. The green floater was included in a petition for listing of 404 southeastern species submitted to the USFWS in April 2010 by the Center for Biological Diversity (USFWS 2021b). Additional information on the green floater is provided in Section E.9.1.5.2.

During a riparian habitat assessment conducted at the Byllesby-Buck Project in April 2017, it was reported to Appalachian (and in turn reported to VDWR, USFWS, and FERC) that a weathered, dead shell of a green floater was found on a dry gravel bar along the New River, upstream of the Byllesby Dam (correspondence from W. Baltzersen of Environmental Solutions & Innovations, Inc. [ESI] to Appalachian, dated May 2, 2017).

Mussel salvage and relocation activities were conducted in the Byllesby reservoir from April 30-May 1, 2018, during a planned reservoir drawdown for the Obermeyer gate replacement at Byllesby Dam (Stantec 2018a). The mussel salvage and relocation efforts were performed along 500-m-long areas of the exposed channel margins above Byllesby Dam. Search areas were surveyed, and where suitable substrates were observed, a visual search for mussels was performed. Four live mussels, three purple wartyback and one green floater, were identified and measured (Table E.9-5), and then relocated upstream of the impoundment in areas with suitable substrate with a similar mussel assemblage.

E.9.1.4 Invasive Aquatic Species

Invasive species are those which do not naturally occur in a specific area and cause ecological and economic damage. Invasive aquatic species of concern to the Project are discussed in the following sections.

E.9.1.4.1 Alabama Bass

The presence of Alabama Bass (*Micropterus henshalli*), a species of black bass that is native to Alabama and Georgia, has recently been confirmed in Claytor Lake (VDWR 2020). Alabama Bass are an aggressive species that outcompetes native Largemouth Bass and frequently hybridize with Spotted Bass and Smallmouth Bass where they co-occur. Although this species has not been documented previously within the Byllesby or Buck Project boundaries, it is feasible that the Alabama Bass will eventually move further upstream into the lower reach of the Project Boundary, below Buck Dam. However, even if this species expands its range further upstream in the New River, it is unlikely to establish within the Project Boundary, downstream of Buck Dam due to a lack of their preferred deep pool habitats. Further, Buck Dam serves as a barrier of further upstream movement of this non-native potentially invasive fish, thus Alabama Bass are not anticipated to be collected within the Byllesby Project Boundary. Due to their potential to impact native fish through competition and hybridization, VDWR requested that pelvic fin clips and lateral line scale counts be collected from specimens of Alabama Bass, should they be collected during fish the 2020 fish sampling efforts. No Alabama Bass were collected during the fisheries surveys performed for the Project in 2020 and 2021 (see Section E.9.2.1.2).

E.9.1.4.2 Northern Virile Crayfish

The invasive Northern Virile Crayfish have been documented throughout the New River (DTA 2008). It is found in streams with moderate flow and turbidity, abundant cover, and stable water levels. It is believed that anglers use of this species as a live bait has been a major factor contributing to its spread throughout the country (USFWS 2015a). The Northern Virile Crayfish are known to modify aquatic macrophyte and macroinvertebrate communities, which in turn can lead to a decline and reconfiguration of the fish community. They may also consume eggs of sunfish, Bluegill, and other fish leading to reduced population sizes. As described above in Section E.5.3.1 and in Section 5.4.5 of the PAD, this species dominated overall densities of crayfish observed in the 2008 crayfish survey conducted in the New River for the Claytor Project relicensing (DTA 2008).

As part of the recent Fries Project relicensing studies, crayfish surveys were completed using a variety of sampling gear and methodologies (e.g., kick-net, seine-haul, D-frame dip nets, and snorkel surveys) (Carey et al. 2017). Although more than 800 live Spiny Stream Crayfish were collected within the study

reaches upstream and downstream of the Fries Project, no Northern Virile Crayfish were collected from within the Fries Project Boundary.

The Northern Virile Crayfish has not previously been documented within the Project Boundary. Given the potential environmental impact of this invasive species, the VDWR was interested in understanding their current distribution near the Project. At the request of VDWR in Scoping Document 2 (dated November 11, 2019), Appalachian included survey efforts for crayfish with the macroinvertebrate study in the Project RSP.

E.9.1.5 Threatened or Endangered Aquatic Species and Aquatic Species of Special Concern

E.9.1.5.1 Candy Darter

The Candy Darter is endemic to the upper Kanawha River basin and is found in the New River drainage basin. The Candy Darter was federally listed as endangered in the Federal Register (83 FR 58747) on November 21, 2018 (USFWS 2018a). The Candy Darter prefers rock, rubble, or gravel riffles in creeks or small to medium rivers (Rohde et al. 1996). Five watersheds that contain known Candy Darter habitats were listed as critical habitat when the USFWS finalized the critical habitat designation for the species on April 7, 2021 (USFWS 2021a); all five watersheds are tributaries to the New River. The critical habitat nearest to the Project is the Cripple Creek tributary, which confluences with the New River 5 RM downstream of Buck Dam.

Extant populations of Candy Darter are currently threatened from a variety of factors including in habitats where they co-occur with the Variegate Darter (*Etheostoma variatum)* which hybridizes with this species, swamping the gene pool. Five watersheds, located in the Ridge and Valley physiographic province, and that contain known Candy Darter habitats are listed as critical habitat; all five watersheds are tributaries to the New River (USFWS 2018a). The nearest critical habitat to the Project is Cripple Creek, which confluences with the New River 5 RM downstream of Buck Dam. The Ridge and Valley province terminates just upstream of Cripple Creek, and Candy Darter are not known to occur upstream of this location, currently or historically. No Candy Darter were collected during recent fish sampling activities within the Project Boundary.

E.9.1.5.2 Green Floater

The green floater is a small, dull yellow to brownish green mussel with a subovate to trapezoidal shape. Shells, especially of younger specimens, may exhibit dark green rays of variable width. Green floater shells are quite thin and when held up to the light, the colors and patterns of the periostracum may be visible through the nacre. The green floater is a hermaphroditic species with a reproductive season extending from August to May. Host fish species have not been determined for the glochidial life stage;

however, prior research documented direct transformation of glochidia into juvenile mussels (Barfield and Watters 1998; Lellis and King 1998). The historical distribution of the green floater is from the Cape Fear River Basin in North Carolina to the Hudson River Basin, to the Genesee River of New York, and includes the New and Greenbrier Rivers in Virginia, West Virginia, and North Carolina.

The green floater was included in an April 2010 petition for listing of 404 southeastern aquatic species submitted to the USFWS by the Center for Biological Diversity. The USFWS is currently reviewing the petition for listing and by the end of fiscal year 2021, expects to make a listing determination for the green floater (USFWS 2021b). The green floater is listed as threatened in Virginia (VDWR 2021).

E.9.2 Environmental Analysis

E.9.2.1 Studies in Support of the Current Relicensing

Several studies related to Aquatic Resources were carried out in support of the current relicensing, including the (1) Bypass Reach Flow and Aquatic Habitat Study, (2) Fish Community Survey, (3) Fish Impingement and Entrainment Study, (4) Macroinvertebrate and Crayfish community Survey, and the (5) Freshwater Mussel Survey. Preliminary results of these individual studies are summarized in the sub-sections that follow and will be reported detailed in the USR and associated appendices. All but the Bypass Reach Flow and Aquatic Habitat Study were prepared by HDR and Appalachian's sub-consultants (Edge Engineering and Science, LLC [EDGE] and Stantec Consulting Services, Inc).

E.9.2.1.1 Bypass Reach Flow and Aquatic Habitat Study

In support of the current relicensing, Appalachian conducted a Bypass Reach Flow and Aquatic Habitat Study in 2020 and 2021. The specific objectives of the study are included below.

- Delineate and quantify aquatic habitats and substrate types in the Byllesby and Buck bypass reaches.
- Identify and characterize locations of habitat management interest located within each bypass reach.
- Develop an understanding of surface water travel times and water surface elevation responses under variable base flow and spillway release flow combinations in the tailrace and bypass reach of each development to:
    - Demonstrate the efficacy of existing ramping rates required by the existing license.[13]

[13] In accordance with existing FERC spillway gate operating requirements for the Buck Development, Appalachian discharges flows through a 2.0-ft gate opening for at least three hours following any spills released through a gate opened 2.0 ft or more. Appalachian must then reduce the opening to 1.0 ft for at least an additional three hours, after which time the gate may be completely closed. The gradual reduction of flow allows time for fish to respond to the receding water levels, thus avoiding stranding that can occur with sudden flow discontinuation.

- Demonstrate the efficacy of the existing powerhouse minimum flow requirement (i.e., 360 cubic feet per second [cfs] minimum flow to maintain aquatic resources, including resident fish species, downstream of each development consisting of the tailrace areas below each powerhouse and the bypass reaches below the main spillways).
- Evaluate the impacts of providing seasonal minimum flows to the bypass reaches.

Bypass Reach Flow and Aquatic Habitat Study Methods

HDR reviewed the hydrologic record for the Project study reaches, spillway and trash sluice gate operating procedures and design capacity, existing topographic and geologic maps, and available recent and historical aerial imagery. Light detection and ranging data (LiDAR) were collected to support development of comprehensive three-dimensional elevation and visual surface layers of the bypass reach. These data were used for desktop mesohabitat mapping of each bypass reach according to substrate size (e.g., sand, gravel, cobble, etc.), cover (e.g., no cover, overhead vegetation, etc.), and mesohabitat types (e.g., pools, riffles, runs, bedrock, shoals). The topographic information was then incorporated as a GIS base layer to support field data collection and hydraulic modeling efforts.

In 2020, field data was collected to support development of a two-dimensional (2-D) hydraulic model of the Buck tailrace and bypass reach. The hydraulic model is based on the Innovyze Infoworks Integrated Catchment Model (ICM) software (version 7.0), which is capable of simulating depth and velocities in a 2-D grid pattern over a wide range of flow conditions. Target model calibration/validation flows were released into the Buck bypass reach in September 2020 for purposes of collecting depth, water surface elevations, velocities, and wetted area data under various bypass flow regimes. For the Buck Development, the target flow scenarios were designed to evaluate the effect of the existing ramping rate requirements. Detailed descriptions of the ICM model development process and results will be provided in the USR.

Similar field data collection efforts under a range of proposed target flows were conducted in the Byllesby bypass reach in 2021. For the Byllesby Development, the target flow scenarios were designed to evaluate the effect of passing the entire minimum downstream flow requirement of 360 cfs through the bypass reach.

The mesohabitat mapping results and the 2-D model depth and velocity simulation results were used in combination with aquatic species habitat suitability criteria (i.e., using depth, velocity, and habitat preferences) to evaluate potential available aquatic habitat in each tailrace and bypass reach under each modeled flow scenario. Walleye was selected as a standalone target species for this study along with a total of eight species-guild representatives including three shallow-slow, one shallow-fast, two deep-slow, and two deep-fast guilds. Guild representatives were selected from a variety of regionally

representative sources, represent a wide range of habitat characteristics, and were selected to represent a wide range of species.

Aquatic habitat modeling is ongoing, and detailed results will be provided in the USR and summarized in the FLA.

Bypass Reach Flow and Aquatic Habitat Study Results

The Buck bypass reach consists of a complex assemblage of aquatic habitat and substrate types, dominated by angular bedrock. The key difference between the Buck upper reach versus the middle to lower reaches is that the orientation of the bedrock slabs is parallel to the flow, which facilitates scour and sediment transport, while the middle to lower reaches are dominated by bedrock slabs oriented perpendicular to streamflow, which facilitates sediment deposition (on the downstream side of the slab). As a result, the Buck upper reach is approximately 50 percent bedrock while the middle to lower reaches, while still dominated by bedrock, contain more smaller-sized particles. The middle to lower transects display zones of sediment deposition and lower-velocity shelters, which create a variety of aquatic habitat for a wider range of aquatic species and life stages.

Surface water travel times and water surface elevation responses were evaluated, and locations of habitat management interest were identified and characterized. The upper portion of the channel along the left descending bank is considered an area of concern from a potential fish stranding perspective. Two level loggers were placed along this channel to evaluate potential impacts to water surface elevations resulting from spillway gate operations. The efficacy of existing ramping rate requirements was also evaluated using water level loggers to capture the impact that ramping rate requirements have on bypass reach water surface elevations. Finally, the efficacy of the existing powerhouse minimum flow requirement was evaluated. The current FERC authorized minimum downstream flow requirement for the Project is 360 cfs. A review of the hydrologic record at the USGS 03165500 New River at Ivanhoe, Virginia flow gaging station from 1996 – 2020 determined that the minimum downstream flow requirement is rarely triggered but did occur during this 25-year period of record in August 2002 (over a 6-day period) and August 2008 (over an 8-day period), corresponding to the two most severe droughts on record.

When the minimum downstream flow requirement is triggered, Project inflows at the Byllesby Development are passed downstream to the bypass reach either via the trash sluice gate and/or one of the Tainter or Obermeyer gates. At the Buck Development, the minimum flow can be passed through the trash sluice gate into the tailrace and/or through a Tainter or Obermeyer gate into the bypass reach. Because the minimum downstream flow requirement is rarely triggered and typically

occurs only during August for about a week at a time, the effect on aquatic habitat is likely negligible at both the Byllesby and Buck developments.

The impacts of seasonal minimum flows were also evaluated using the habitat modeling results for the various habitat guilds and standalone Walleye species/life stages. Spawning life stages were of particular interest since there is a seasonal component to this life stage.

This Bypass Reach Flow and Aquatic Habitat study is ongoing at both developments and study results will be reported in detail in the USR and summarized in the FLA.

E.9.2.1.2 2020-2021 Fish Community Survey

Study scoping with state and federal agencies early in the relicensing process resulted in the development and approval of a project-specific RSP that identified two objectives for the Fish Community Survey:

1. Collect a comprehensive baseline of existing aquatic resources near the Project
2. Compare recent aquatic resource data to historical data to identify changes or trends of significance to species composition or abundance

To achieve these objectives, a Fish Community Survey consisting of a spring and fall sampling effort was scheduled to begin in Spring 2020 as originally proposed in the RSP. However, spring sampling activities were not accomplished during the 2020 calendar year due to delays resulting from unforeseeable circumstances including heavy precipitation and high flows and the COVID-19 global pandemic. Boat electrofishing and gill net sampling was completed during fall 2020, but the ongoing weather delays resulted in the fall 2020 backpack electrofishing methods being rescheduled for spring 2021; therefore, an ISR covering the fall 2020 sampling effort was submitted on January 18, 2021. The spring fish sampling activities were completed successfully in 2021, and the combined results of the fall 2020 and spring 2021 efforts are summarized in the following sections and will be detailed in the 2020-2021 Fish Community Survey Results, to be provided in the USR.

At the initiation of sampling in fall 2020, multiple proposed locations did not correspond well with the habitat targets identified during the desktop-based site selection process. As such, sampling methods for those locations were adjusted in the field to provide the best possible sample collection effort from the sampling locations identified in the RSP. Two sites upstream of a high gradient riffle complex, located between Byllesby and Buck dams, and originally identified as boat electrofishing sites were switched to backpack electrofishing methods based on the presence of boulder habitat with swift currents. One proposed backpack electrofishing site (at the mouth of Crooked Creek in the Byllesby

pool) was replaced with boat electrofishing methods as the site consisted of pool habitat and was not conducive to backpack electrofishing methods.

Boat electrofishing and gillnet sampling techniques were employed to target specific sites based on the habitat types present in the Project area. Boat electrofishing was used to target near shore pool habitats and gillnetting targeted mid-channel pool habitats. Seven boat electrofishing sites were located in the Byllesby pool and 10 were located in the Buck pool. Six gillnetting sites were located in the Byllesby pool to target Walleye. Field sampling activities were completed during relatively low flow and clear stream conditions by state permitted fish biologists covered under EDGE's Virginia Scientific Collecting Permit No. 068630.

Fish Community Survey Methods

Boat Electrofishing

Each boat electrofishing site consisted of a 100-m-long transect marked with start and endpoint coordinates with a GPS unit. At each sample site, habitat characteristics (e.g., substrate, estimated water velocity, depth, and instream cover) and water quality parameters (e.g., pH, water temperature, DO, and conductivity) were measured and recorded. In addition, a Secchi disk reading was taken at each sample site at the time of sampling. Multiple points for habitat and water quality measurements were taken if there was large variation within a single site. Prior to initiating sample collection, electrofishing equipment was calibrated based on the water conductivity at each sample site. Sampling effort (i.e., time electrofishing) was also recorded during each sampling event.

Starting at the downstream end of the transect and moving upstream, all available habitat types (i.e., shallow shoreline, deep shoreline, emergent vegetation, submerged wood, etc.) were candidates for sampling throughout the reach and particular care was taken to thoroughly sample complex habitat and instream structures. For each 100-m transect, a minimum of five minutes electrofishing was performed unless habitat complexity necessitated additional time. Fish samples were held in a live well until sampling and sample processing were completed at each site. Each fish was identified to the lowest taxonomic level practicable, enumerated, and examined for signs of external parasites, disease, or physical abnormalities. In addition, total length (TL) and weight were recorded for the first 30 individuals of a species per sample site. In the event that more than 30 individuals of a single species were collected at a given sample site, the additional fish were counted, and length measurements were recorded for specimens that exceed the upper or lower maximum recorded lengths from the 30 individuals previously measured. Photos were taken in the field for a representative specimen of each fish taxon collected during the study and for those fish that could not be identified to species (e.g., minnows, juvenile *Moxostoma sp*.), representative specimens were preserved and identified in a laboratory setting based on sampling permit specifications. When Spotted Bass and/or

suspected Alabama Bass were captured, a voucher photo was taken and a thumbnail-sized portion of one of the pelvic fins was clipped and stored dry in an envelope (along with length and weight) for VDWR notification.

Backpack Electrofishing

Backpack electrofishing surveys were performed at 13 riffle/run sites along 100-m transects (or two 50-m transects if habitat was limited longitudinally). Backpack electrofishing transects were delineated in riffle/run habitat and the start and endpoint coordinates were recorded. Site photos, field conditions, habitat characteristics, and water quality parameters were recorded in the same manner as boat electrofishing sites. Multiple data points were collected for habitat and water quality measurements when large variation was observed within a single site. Prior to initiating sample collection, electrofishing equipment was calibrated based on the conductivity of stream water at each sample site. Sampling effort (i.e., electrofishing time) was also recorded during each sampling event.

Starting at the downstream end of the transect and moving upstream, all major riffle/run habitats along the transect were sampled and particular care was taken to thoroughly sample complex habitat and instream structures, while a netter(s) actively captured stunned fish with a dip net. In areas of elevated stream velocities, a stationary seine (2.4 m wide by 1.8 m tall with 0.48-cm mesh) was positioned downstream of the sample location perpendicular to stream flow. The operator of the backpack electrofishing unit performed kicks/sweeps of the transect while working in a downstream manner toward the seine, driving fish toward the seine net. Stunned fishes were driven into the net with the aid of stream currents and the seine was then swept upward and fish retrieved for processing. For each 100-m transect, a minimum of five minutes electrofishing time was expended, with additional time added when necessary depending on the complexity of the habitat. Collected fish were kept in aerated buckets and/or instream live wells during surveys and processed in the same manner as boat electrofishing methods (described above in Boat Electrofishing section) before being returned to the stream at the survey location.

Gillnetting

Gillnetting techniques were used to survey the fish community at six pool sites (i.e., BFG site names) with 36.5-m-long by 2.4-m-deep gillnets. Each gillnet was comprised of eight 4.6-m-long panels with mesh sizes of 1.9, 2.5, 3.2, 3.8, 5.1, 6.4, 7.6, and 10.2 cm, and nets were anchored so that the top of the net was at least 0.5 m below the surface. Starting on the shoreward side, and with the smallest mesh size, gillnets were pulled taught as the boat operator moved towards the channel and slightly downstream of and perpendicular to shore. The start and endpoint coordinates were recorded for each gillnet deployment. Site photos, field conditions, habitat characteristics, and water quality parameters

were recorded in the same manner as boat electrofishing sites. Nets were set for 24 hours before they were retrieved with a grappling hook and checked for fish, which were placed in live wells for processing. Nets were reset in the same location and fish were processed in the same manner as boat electrofishing methods (described above in Boat Electrofishing section), except processed fish were released at least 100 m from the site so they did not immediately become entangled when the gillnets were reset. Nets soaked for another 24 hours and were checked again and pulled from the location after a total of 48 hours of soak time per site.

Fish Community Survey Results

Boat electrofishing surveys were conducted according to methods outlined in the RSP between October 22 and 24-25, 2020, and April 25-26 and May 27, 2021. Backpack electrofishing surveys were conducted between April 20-23, 2021. Gillnet surveys were conducted between November 9-11 and 18-20, 2020, and April 20-24, 2021. Sample collection occurred during relatively low-flow and clear stream conditions. Results of physiochemical data collected at sample sites met the state water quality standards established for the New River, indicating that water quality within the Project area is capable of supporting fish communities.

A total of 404 fish representing 26 distinct species were collected upstream of Byllesby Dam from seven boat electrofishing sites (sampled fall 2020 and spring 2021), three backpack electrofishing sites (sampled spring 2021), and six gillnet sites (sampled fall 2020 and spring 2021). Five of the 26 species collected were found exclusively upstream of Byllesby Dam. A total of 509 fish representing 33 species were collected from 10 boat electrofishing sites (sampled fall 2020 and spring 2021) and six backpack electrofishing sites (sampled spring 2021) located between Byllesby Dam and Buck Dam. Seven fish species were collected exclusively between Byllesby Dam and Buck Dam. A total of 206 fish representing 17 species were collected from four backpack electrofishing sites (sampled spring 2021) below Buck Dam. Two species were collected exclusively below Buck Dam).

The fish community results were divided and analyzed in three distinct sections to facilitate an evaluation of potential differences in the fish community throughout the Project Area – upstream of Byllesby Dam, between Byllesby Dam and Buck Dam, and downstream of Buck Dam. Backpack electrofishing results (from spring 2021) were compared between these three sections. Boat electrofishing results (from fall 2020 and spring 2021) were compared between the Byllesby pool and Buck pool. Gillnetting results in the Byllesby pool were primarily used to investigate the presence and distribution of Walleye. Understanding how the fish community changes throughout the Project area provides insight into the impact, or lack thereof, that the Project has on the New River.

Boat Electrofishing - Byllesby and Buck Reservoirs

The substrates at boat electrofishing sites in the Byllesby and Buck impoundments were comparable; with both pools predominantly consisting of sand (>60%), silt (20%), and a mix of gravel (5%) and boulder (5-15%). The left descending bank of both pools were characterized as low-gradient, with a vegetated floodplain; while the right descending bank exhibited a high-gradient, rock face. The Byllesby pool and the lower reach of the Buck pool exhibited steep banks, while the banks along the upper reach of the Buck pool were shallow, and gently. Both pools exhibited very little habitat structure, with sparse woody debris, submerged aquatic vegetation, and scattered boulders. Water quality parameters (temperature, pH, DO, velocity, and conductivity) remained relatively consistent throughout the Byllesby and Buck impoundments; however, slightly higher velocities (Byllesby and Buck) and increased DO (Buck) were documented near the head of the impoundment.

A total of 244 fish (20 species) were collected in the Byllesby pool from seven boat electrofishing sites, compared to 353 fish (24 species) in the Buck pool from 10 boat electrofishing sites. The most abundant species collected during boat electrofishing surveys in the Byllesby reservoir were Telescope Shiner (*Notropis telescopus*) (29.5%), Bluegill (15.2%), and Redbreast Sunfish (9.8%); however, Telescope Shiner were only collected at one site. The most abundant species collected in the Buck pool were Redbreast Sunfish (28.9%), Smallmouth Bass (20.4%), and Whitetail Shiner (*Cyprinella galactura*) (11.6%), each of which being captured at a minimum of five sites. Distribution of individuals was relatively consistent throughout each pool and correlates with habitat preference and complexity. The Byllesby pool was dominated by the invertivore-piscivore trophic guild and the water column habitat guild, whereas the Buck pool was dominated by the invertivore trophic guild and the water column habitat guild (McCormick et al. 2001).

Shannon's diversity index (H') is a measure of diversity that combines species richness (the number of species in a given area) and their relative abundances. Boat electrofishing sample data were to facilitate the calculation and comparison of (H') for and between the Byllesby and Buck impoundments. Overall, species diversity resulting from boat electrofishing surveys was negligibly higher in the Byllesby pool (H' = 2.32) than in the Buck pool (H' = 2.26). CPUE ranged from 0.3 to 14.2 individuals per minute in the Byllesby pool (averaging 2.9) and CPUE ranged from 0.5 to 9.5 individuals per minute in the Buck pool (averaging 2.8). CPUE was 54 percent higher in the spring than the fall in the Byllesby pool and 214 percent higher in the spring than the fall in the Buck reservoir.

Backpack Electrofishing

The substrate at backpack electrofishing sites located in the upper reach of the Byllesby impoundment (above Byllesby Dam) and Buck impoundments (tailrace and bypass channel below Byllesby Dam)

generally consisted of bedrock (25 to 35%), boulder (25%), cobble (20%), gravel (15%), and sand (5 to 15%). Habitat structure at these sites primarily consisted of well-developed, swift riffles varying from a few centimeters to a meter in depth, with substrates consisting of bedrock, cobble, and gravel. Backpack electrofishing samples were collected from all types of riffle/run habitat present in both areas, from low-gradient riffles with relatively small substrate and no instream cover to high-gradient riffles with relatively large substrate and substantial instream cover. In the bypass channel downstream of Buck Dam, the percentage of bedrock increased (35%) and the percentage of sand (5%) decreased in comparison to substrates above and below Byllesby Dam. Sample sites downstream of the Buck Bypass Reach were located in run to riffle-run habitats adjacent to undercut banks and overhanging vegetation, with substrates dominated by bedrock (25%), boulder (25%), cobble (20%), gravel (15%), and sand (15%). Water quality parameters (temperature, pH, DO, velocity, and conductivity) remained relatively consistent throughout all backpack electrofishing sites except velocity, which often changes dramatically within a short distance in response to the complex substrate and habitat structure.

A total of 48 fish (11 species) were collected upstream of the Byllesby Dam from three backpack electrofishing sites, compared to 156 fish (18 species) in six sites between the Byllesby Dam and Buck Dam, and 206 fish (17 species) from four sites downstream of the Buck Dam. The most abundant species collected upstream of the Byllesby Dam were Whitetail Shiner (39.6%) and Rosyface Shiner (16.7%), with Whitetail Shiner being the only species captured at all three sites. The most abundant species collected during backpack electrofishing surveys between the Byllesby Dam and Buck Dam were Telescope Shiner (43.6%) and Whitetail Shiner (14.7%). The least productive site, which accounted for only 2.5% of total abundance, between Byllesby and Buck dams was in the Bypass Reach. The most abundant species collected below Buck Dam during backpack electrofishing surveys were Central Stoneroller (28.6%) and Telescope Shiner (25.7%). The complex habitat in the Buck Dam Bypass Reach resulted in the collection of 142 fish, compared to only 14 fish collected from the bedrock dominated Byllesby Dam Bypass Reach.

Overall, species diversity resulting from backpack electrofishing surveys was comparable between the sites upstream of the Byllesby Dam, between the Byllesby Dam and Buck Dam, and downstream of the Buck Dam (H’ = 1.92, 1.97, and 1.98, respectively). In contrast, the average CPUE for sites upstream of the Byllesby Dam was 1.7 individuals per minute, between the Byllesby Dam and Buck Dam was 3.5 individuals per minute, and downstream of the Buck Dam was 7.6 individuals per minute. The doubling of CPUE moving downstream through the Project area may have resulted from increasing complexity and availability of habitat or efficacy of sampling techniques in select habitats. However, it is also understood that dams can serve as barriers to upstream fish migration, impacting species abundance and/or distributions, thus abundance may generally increase in the downstream direction in some rivers.

Gillnetting

The substrate at gillnetting sites within the Byllesby reservoir generally consisted of sand (70%), silt (25%), and gravel (5%); however, the near-shore substrates ranged from vertical rock face and boulder to sand and silt flats. Sample sites located along the left descending bank were low gradient and adjacent to vegetated floodplains, while sample sites on the right descending bank were located in high gradient areas adjacent to steep faced rock outcrops.

A total of 112 fish representing 10 species were collected from gillnet sites in the Byllesby reservoir. No fish were collected from one of the gillnet sites which was set in an area with relatively swift current within the thalweg of the river, on the outside bank of a meander, and may not be suitable for consistent fish utilization. The gillnet surveys in the Byllesby reservoir were dominated by Common Carp (51.8%), Channel Catfish (24.1%), White Sucker (8.0%), and Walleye (8.0%). Distribution of individuals was relatively consistent throughout the Byllesby reservoir and likely correlates with habitat preference and complexity; however, a large majority of the Common Carp (most abundant species) were collected at one site.

Overall, species diversity (H' = 1.43) resulting from gillnetting surveys in the Byllesby reservoir was relatively low, although there were no direct comparisons to be made as gillnetting did not occur anywhere else in the Project area. CPUE ranged from 0.5 to 22 individuals per net set (averaging 6.2), and like boat electrofishing methods, CPUE was 62% higher in spring than in fall.

Fish Community Survey Conclusions

The two-development Project is in a rural area within a relatively large watershed, which may contribute to potential issues pertaining to water quality and habitat degradation in this portion of the New River that are independent of the Project. The Project has historically influenced habitat availability through formation of two reservoirs (creating pool habitat and eliminating riffle habitat), which dictates what species inhabit the Project area. However, the habitats present within the Project area appear to support a relatively diverse fish community with little evidence of physical abnormalities or stressors.

Twenty species were collected using boat electrofishing from seven sites in the Byllesby reservoir, and 24 species were collected from 10 sites in the Buck reservoir; however, species diversity was negligibly higher in the Byllesby reservoir than in the Buck reservoir and CPUE was nearly identical. The additional species may be attributable to a greater number of sites being surveyed or slight differences in habitat availability. Overall, the Byllesby reservoir and Buck reservoir exhibit similar fish community characteristics. Boat electrofishing yielded two game fish species in the Byllesby reservoir that were not present in the Buck reservoir (i.e., Muskellunge and Rainbow Trout [*Oncorhynchus*

mykiss]). In contrast, boat electrofishing in the Buck reservoir yielded nine species (darters, minnows, shiners, suckers, and sunfish) that were not present in the Buck reservoir.

With regards to backpack electrofishing, 11 species were collected upstream of the Byllesby Dam from three sites, 18 species were collected between the Byllesby Dam and Buck Dam from six sites, and 17 species were collected downstream of the Buck Dam from four sites. These differences in species richness may result from differences in effort between the Project areas; however, differences in species diversity were negligible between each Project area. The general abundance of fish in riffle/run habitats increased in the downstream direction, with CPUE doubling from upstream sites to middle sites and doubling again from middle sites to downstream sites. No fish species were exclusively collected using backpack electrofishing methods upstream of Byllesby Dam; however, Kanawha Darter and Saffron Shiner (*Notropis rubricroceus*) were only collected between Byllesby and Buck dams and Kanawha Sculpin and White Shiner were only collected downstream of Buck Dam.

Gillnetting methods were only implemented in the Byllesby reservoir, by request from VDWR, to target Walleye, which was the only species of fish exclusively captured using gillnets. A total of nine Walleye were captured at three of six gillnet sites, characterized as low gradient sites with substrates consisting primarily of sand and silt. Further, the three sites where Walleye were captured were in the upper, middle, and lower sections of the Byllesby reservoir, indicating that they are using most of the impoundment at some point. Six Walleye were collected in fall 2020 and three were collected in spring 2021. Six of the nine Walleye were collected at the downstream most site in the Byllesby impoundment, indicating that they may be occupying the deeper sections more often.

In a historical study of the Project area, Appalachian (1991b) employed boat electrofishing, gillnetting, and hoop netting techniques. Although they did not use backpack electrofishing techniques, they used boat electrofishing techniques in both pool and riffle habitat. The historical study sampled a similar number and distribution of sites throughout the Project area. Both the current study and Appalachian (1991b) sampled a total of 36 sites using differing techniques; however, the previous study collected samples six times at each site for a total of 216 samples, whereas the current study only sampled fall and spring resulting in 59 total samples. Additionally, for each pair of sites surveyed in Appalachian (1991b), one was sampled during the day and the other at night. The current study did not include nighttime electrofishing due to safety concerns.

In Appalachian (1991b), a total of 2,679 individuals were collected representing 34 species. The current study collected 1,119 individuals representing 40 species. Therefore, although the survey effort differed, there was an increase in overall richness of fish species within the Project area. Both studies yielded a low incidence of parasites and physical abnormalities. Four species were captured in the previous study that were not captured in the current study and 11 species, including Walleye, were

captured in the current study that were not captured in the previous study. The overall diversity of the fish community was greater in the current study (H'=2.91) than in the previous study (H'=2.53). Smallmouth Bass and Redbreast Sunfish were two of the four most abundant species in both studies and many of the other mutual species were found in similar relative abundance. Neither study collected any federally or state listed threatened or endangered species. Overall, distribution of fish abundance and richness throughout the Project area during the current study closely matched that of Appalachian (1991b). For example, the highest average CPUE and richness per sample for riffle/run habitat was recorded downstream of the Buck Dam.

For the purposes of this study, a comparison of species richness at boat electrofishing sites in 2020/2021 and Appalachian (1991b) were used to help identify any trends in the fish community within the Project area. Species richness observed in the current study during boat electrofishing in pool habitats were 20 species and 24 species in the Byllesby impoundment and Buck impoundment, respectively. Species richness observed in the previous study during boat electrofishing in pool habitats were 9 species and 11 species in the Byllesby impoundment and Buck pool, respectively. Overall, fish community composition was quite similar between the two studies, but richness in the study area seems to have increased indicating that the New River within the Project area continues to support an abundant and diverse fish community.

E.9.2.1.3 Impingement and Entrainment Study (Preliminary Results)

An assessment of entrainment and impingement potential at each of the Project developments was performed in accordance with the RSP and the Commission's SPD, as summarized in the follow section. The detailed report with final results and conclusions will be provided in the USR and also summarized in the FLA.

A turbine blade strike evaluation, as proposed in the RSP and modified to also cover the turbine upgrades now proposed by Appalachian, is currently being developed and results from the analysis will be provided in the USR. The analysis is being performed using the most recent version available of the USFWS Turbine Blade Strike Analysis Model (USFWS 2020), mean and standard deviation of fish lengths based on fish data collected during the 2020-2021 Fish Community Study, and site-specific inputs for required model parameters.

Information on the physical and operational characteristics of the Project, including trashrack bar spacing, intake velocities and flows, and intake proximity to feeding and rearing habitats was used to determine the impingement and entrainment potential at the Project using a desktop study approach. A species list was developed based on data from recent and historical (Appalachian 1991b) fish community studies (i.e., composition, abundance, listed or protected status, recreational significance),

as well as known occurrence records from the VDWR for the New River at the time of the historical fish community study.

With consideration of site-specific facility characteristics and fishery information, detailed entrainment data from 33 sites included in the Electric Power Research Institute (EPRI) (1997) entrainment database were applied in this analysis. Entrainment data were standardized to the number of fish/hour of unit capacity based on the site-specific hydraulic capacity of the sampled units and the number of hours sampling occurred during each of the database studies, and then used to calculate fish entrainment rates (fish/hour) at the existing maximum design turbine discharge at the Project (5,868 cfs for the Byllesby Development and 3,540 cfs for the Buck Development).

Using the Byllesby intake opening structure dimensions, the calculated approach velocity in front of the intake is approximately 2.0 ft per second (fps) (i.e., 5,868 cfs/(143 ft x 14 ft x 1.5)). This approach velocity is consistent with the value presented in the historical Project entrainment report (Appalachian 1991b). Burst swim speeds for target or representative species were compared to the estimated intake velocity to evaluate whether fish may be susceptible to intake flows at the Project. Using the Buck intake opening structure dimensions, the calculated approach velocity in front of the intake structure is approximately 1.6 fps (i.e., 3,540 cfs/(104 ft x 14 ft x 1.5)).

Fish swim burst speeds obtained from literature indicate that all target species and life stages evaluated, with the exception of eggs, larvae, and juvenile Spottail Shiner, would be able to avoid entrainment at the Project given that estimated swim burst speeds are greater than approach velocities at the intake. Although most species were considered of entrainable size (i.e., smaller than the 2.28- inch clear-spacing width of the trash racks at both Byllesby and Buck), it is likely that juvenile and adult fish can avoid the intake.

According to the EPRI (1997) database, fish measuring less than six inches in length were the majority (88 percent) of entrained fish, and fish less than eight inches exhibit the highest entrainment rates throughout the year. Rock Bass, catfishes, suckers and redhorses, *Lepomis* sunfishes, and Black Crappie, Largemouth Bass, darters and logperch, and shiners, chubs, and minnows represent the top 90 percent of target species and species groups potentially susceptible to entrainment at the Byllesby and Buck developments. Peak months of entrainment for these species and species groups varied. Smallmouth Bass, Walleye, and Muskellunge, species often sought after by anglers, have some of the lowest entrainment rates of the target species and groups. Entrainment rates were highest from April to October, with peaks in April, July, and October. Peaking months may correspond to spawning movements (April), recruitment to catchable size (July or October), or large storm/flow events. Susceptibility to entrainment is variable depending on species and time period, however most target species and species groups have low entrainment potential for most of the year.

While the greatest opportunity for fish mortality through a facility lies in potential contact with the turbine runner blades, injuries and mortalities can result from other mechanisms including extreme pressure changes, shear stress, water turbulence, cavitation, and grinding (Deng et al. 2005); however, the historical study (Appalachian 1991b) determined that these factors are minimal at the Project. Since no significant changes have occurred at the facility that would change these parameters since the last relicensing, injuries and mortalities caused by factors other than turbine strikes are expected to be negligible.

In summary, the findings of the current study concur with the historical entrainment study completed for the prior relicensing in that effects to the fish community in the Project vicinity are expected to be minimal. Most fish would not be excluded by the intake trashracks at Byllesby and Buck intake structures; however, velocities in front of the intakes are comparable to normal flow conditions of the New River and would therefore likely be navigable by most juvenile and adult fish in the area. Entrainment of early life stage fishes (eggs and larvae) is likely minimal given the life history characteristics of species in the vicinity of the Project. Susceptibility to entrainment is variable depending on species and time period, however most target species and species groups have low entrainment potential for most of the year.

E.9.2.1.4 2020-2021 Macroinvertebrate and Crayfish Community Survey

On behalf of Appalachian, EDGE conducted a Benthic Aquatic Resources Study to document a comprehensive representation of the Project area and to correlate with previous sampling efforts (Appalachian 1991a) for comparison. Macroinvertebrate and crayfish sampling efforts targeted representative habitat at 16 sites throughout the Project area using sampling methods derived from the National Rivers and Streams Assessment Field Operations Manual and VDEQ Biological Monitoring Program Quality Assurance Project Plan and included quantitative and qualitative sampling methods that target different habitats (USEPA 2019; VDEQ 2008). Quantitative sampling methods targeted riffle/run habitats and qualitative sampling methods targeted available microhabitats in pools habitats. Sampling was performed by an EDGE state and federally permitted astacologist under Virginia Scientific Collecting Permit No. 068630. All macroinvertebrate sites were sampled between October 6 and 8, 2020 during the fall sample index period defined by VDEQ (September 1 – November 30) (VDEQ 2008). The spring 2020 sampling effort was completed during the spring 2021 index period (March 1 – May 31).

Macroinvertebrate and Crayfish Community Survey Methods

Quantitative Sampling

Benthic macroinvertebrate and crayfish sampling efforts were completed at eight riffle/run sites along 100-m transects. Macroinvertebrate sampling was conducted holding the D-frame net on the bottom of the stream perpendicular to flow and kicking substrate to agitate and dislodge organisms, thus allowing dislodged organisms to flow into the net. A single quantitative sample consisted of a composite of six kick sets, each disturbing approximately 0.33 m^2 above the dip net for a duration of 30-90 seconds and totaled an area comprising 2.0 m^2. For quality assurance measures, replicate sampling was conducted at one quantitative site within close proximity (not in the same locations as the first set of samples) of the initial sampling area.

To assess the crayfish community, additional kick samples and seining efforts were performed following benthic macroinvertebrate sampling to ensure all crayfish habitat had been covered.

Qualitative Sampling Methods

Benthic macroinvertebrate and crayfish were also sampled at five qualitative sites (i.e., multi-habitat) along 100-m transects following guidelines defined by USEPA (2019) and VDEQ (2008). Sampling was conducted by performing 20 jabs with a D-frame net into suitable, stable habitats (snags, vegetation, banks, and substrate) 20 times. A single jab consists of forcefully thrusting the net into a microhabitat for a linear distance of 1.0 m, followed by 2-3 sweeps of the same area to collect dislodged organisms for 20-90 seconds per jab, sweep, or kick. Different types of habitat were sampled in rough proportion to their frequency within the reach. Sampling effort was proportionally allocated (20 jabs/sweeps/kicks) to shore-zone and bottom-zone, 20-90 seconds per jab, sweep, or kick.

Macroinvertebrate and Crayfish Community Survey Results

Benthic macroinvertebrate and crayfish community metrics can be used as indicators of water quality, as these organisms often exhibit sensitivity to changing water quality conditions, and because they serve as a food resource for fish and other fauna in the riverine community. A healthy stream generally includes habitat diversity and limited pollution, often indicated by a high VSCI and HBI score (standard biological metrics).

Macroinvertebrate samples were collected from 16 sites between October 6 and 8, 2020, during the fall sample index period (September 1 – November 30) and between April 20 and 23, 2021, during the spring sample index period (March 1 – May 31), as defined by VDEQ (2008). Sampling was performed by EDGE's state and federally permitted astacologist under Virginia Scientific Collecting Permit No. 068630. The physiochemical data from each of the sample sites met the state water quality standards

established for the New River (VAC Chapter 260), indicating that water quality conditions within the Project area are capable of supporting macroinvertebrate communities. Additional water quality data are provided in the Water Quality Study Report provided in the Project USR.

A total of 49 macroinvertebrate taxa were collected upstream of Byllesby Dam from two quantitative sites and four qualitative sites, along with the Spiny Stream Crayfish, which was collected from a qualitative site near the dam. The average VSCI score for sites sampled upstream of Byllesby Dam in fall 2020 was 41.9 (impaired), and only a single site resulted in a "similar to reference" score above 60, with a score of 62.7. However, four sites above Byllesby Dam had HBI values indicating "Good" to "Excellent" water quality. In spring 2021, one site upstream of Byllesby Dam had a VSCI score greater than 60, with a score of 75.1. The average VSCI score for all sites above Byllesby Dam and for both sampling seasons was 38.0. Similar to the fall sample, four sites in this Project area had HBI values indicating "Good" to "Excellent" water quality based on the tolerance of the macroinvertebrate community.

A total of 53 macroinvertebrate taxa were collected between the Byllesby Dam and Buck Dam from four quantitative sites and four qualitative sites. The average VSCI score for sites sampled between the Byllesby Dam and Buck Dam in fall 2020 was 52.5 (impaired); however, four sites (three quantitative and one qualitative) resulted in a "similar to reference" score above 60. Four sites in this section of the Project area had HBI values indicating "Good" to "Excellent" water quality. In spring 2021, only three sites resulted in a VSCI score greater than 60, and the average VSCI score for sites between Byllesby and Buck dams was 46.5. In contrast to the fall sample, seven of eight sites in the area between Byllesby and Buck dams had HBI values indicating "Good" to "Excellent" water quality based on the tolerance of the macroinvertebrate community.

A total of 30 macroinvertebrate taxa were collected from two quantitative sites located downstream of the Buck Dam. The average VSCI score for sites sampled downstream of the Buck Dam in fall 2020 was 58.8 (impaired). One of two sites scored above 60 with a total of 63.0, which was classified as "similar to reference", and had an HBI value indicating "Very Good" water quality. However, the HBI value at the downstream site was classified as "Fair". In spring 2021, one of two sites resulted in a "similar to reference" score of 62.2. The average VSCI score for the sites downstream of Buck Dam was 59.0, which is just below the threshold for "similar to reference". In contrast, both sites below Buck Dam in the fall 2020 sample, had HBI values indicating "Very Good" and "Good" water quality based on the tolerance of the macroinvertebrate community.

VSCI scores recorded at each site were greater on average in the fall than in the spring. The average VSCI scores upstream of Byllesby Dam, between Byllesby and Buck Dam, and downstream of Buck Dam all indicated "impaired" conditions during the fall and spring samples. Downstream of Buck Dam

had an overall average VSCI score (58.9) just below the threshold of "similar to reference" conditions (60). During both seasonal collections, the lowest VSCI scores were recorded upstream of Byllesby Dam and the highest were recorded downstream of Buck Dam, which indicates less impairment as you move downstream through the project area. Seven sites throughout the Project area resulted in VSCI scores greater than 60 during at least one season of survey.

One of two species of crayfish was collected upstream of Byllesby Dam, but both species were collected between Byllesby and Buck dam, and downstream of Buck Dam. There were zero crayfish captured at the two quantitative sites upstream of Byllesby Dam and both species of crayfish were captured at both quantitative sites below Buck Dam. These sites had similar substrate and habitat composition and relatively similar physiochemical parameters. Conhoway Crayfish were observed under large boulders both near the bank and further channelward, while the Spiny Stream Crayfish were concentrated within cobble substrates and near shore cover. Overall, the presence of two relatively abundant native crayfish species and zero invasive crayfish species in the Project vicinity may indicate a healthy community.

The mustached clubtail and the pygmy snaketail were identified as species with potential to occur in the Project vicinity by VDCR in a letter dated September 23, 2017. The presence of these "species of greatest conservation need" would indicate relatively high water quality. The pygmy snaketail was collected from the New River near the Fries Project (Carey et al. 2017), which is located approximately 13 river kilometers upstream of the Byllesby-Buck Project. Prior to the present study, no macroinvertebrate data were available for the Project and the presence of the mustached clubtail and pygmy snaketail were unknown for the Project reach of the New River. Although dragonfly larvae were collected during the fall and spring sampling efforts from 2020-2021, no mustached clubtail or pygmy snaketail dragonfly larvae were collected.

Crayfish surveys were also completed as part of the Fries Project, where spiny stream crayfish were the only species collected (Carey et al. 2017); however, prior to the current study, no site-specific information on crayfish populations in the Project reach of the New River were available. Approximately 33 species of crayfish, including non-indigenous and/or invasive species such as the northern virile crayfish, have been documented in waterbodies throughout Virginia (VDGIF 2018; VISAC 2018). The northern virile crayfish was collected at the Claytor Project (DTA 2008) located 70 river kilometers downstream of the Byllesby-Buck Project.

E.9.2.1.5 Freshwater Mussel Community Study

Stantec completed all components of the Freshwater Mussel Survey in 2020 in accordance with the RSP and the Commission's SPD; the study report was provided in the ISR and is summarized below.

Methods used to survey mussels were based on Freshwater Mussel Guidelines for Virginia (USFWS and VDGIF 2018) and consisted of visually identifying potential mussel habitats within the approximately 3,000-m long reach between Byllesby Dam and the Buck impoundment islands as well as the tailrace of Buck Dam. These areas were chosen to fill information gaps based on available data from historic studies completed for the majority of the surrounding habitats (Pinder et al. 2002; Alderman 2008; Stantec 2018a, 2018b). This study did not examine the Buck or Byllesby impoundment pools due to the availability of data from recent studies completed during drawdown activities (Stantec 2018a, 2018b).

To assess the Buck Dam tailrace, exposed riverbanks were observed to identify any spent valves or evidence of suitable mussel habitat. The high velocities and unknown depths in the narrow channel were not conducive for safe in-water surveys such as wading, SCUBA, or snorkeling. Ten areas identified as potential mussel habitats in the reach between Byllesby Dam and Buck impoundment Islands were assessed using wandering timed searches (two shallow shoals, three deep shoals, three pools, and two side channels). Surveyors used SCUBA, surface supplied air diving, and snorkeling to conduct 200-minute wandering searches of the substrates in each area. Search tactics included moving gravel/cobble and woody debris, hand sweeping away silt, sand, and/or small detritus, and disturbing/probing the upper 5 cm of substrate where possible. Total search time was 33.3 hours.

Nine *Cyclonaias tuberculata* were identified during the survey of the ten habitat units. Live mussels were only found in two of the ten surveyed areas and overall mussel densities were lower than the sites downstream of Buck Dam. Quality habitat within the survey area was limited as bedrock and overlying silt deposits were the most predominant substrate types. A reconnaissance level habitat assessment of the Buck Dam tailrace was also conducted. No evidence of spent valves or viable mussel habitat were observed within the Buck Dam tailrace, where high velocities resulting from a narrow, confined channel most likely preclude mussel occupancy.

Existing relevant and reasonably available studies of mussels within the Project area were reviewed and compared to results of summer 2020 field surveys. In total, data from six other mussel surveys conducted within the Project area between 1997 and 2018 were compiled to form a more comprehensive understanding of the mussel community in the vicinity of Project operations. Six species were observed within the Project area: *Cyclonaias tuberculata*, *Eurynia dilatata, Tritogonia verrucosa, Lampsilis fasciola, Lasmigona subviridis,* and *Lampsilis ovata.* Survey sites downstream of Buck Dam (downstream of the confluence of the tailrace and bypass channel) supported the highest density mussel habitats. *Cyclonaias tuberculata* and *Tritogonia verrucosa* were the most abundant species and mussel size data suggests that recent recruitment has occurred for these species. Results

of 2020 field surveys are consistent with findings of historical surveys. High quality mussel habitat within the Project area is limited and does not support a diverse or abundant mussel community.

E.9.2.2 Project Impacts on Aquatic Resources

In SD3, FERC staff identified the following environmental issues to be addressed in their NEPA document:

- Effects of continued project operation and maintenance on water quality, including DO concentrations, water temperature, and turbidity upstream and downstream of each development, including the Buck bypass reach.
- Adequacy of the existing 360-cfs minimum flow for aquatic resources, including resident fish species, downstream of each development (Buck and Byllesby).
- Whether there is a need for a minimum flow (beyond leakage) in the Buck bypass reach.
- Effects of continued project maintenance (periodic impoundment drawdowns to replace flashboards and periodic dredging to remove sediments from the impoundments) on aquatic resources, particularly freshwater mussels and fish spawning habitat in the impoundments of each development.
- Effects of continued project operation on aquatic resources, including entrainment and impingement mortality of resident fishes, such as Walleye, Smallmouth Bass, and Spotted Bass at each development.
- Effects of continued project operation and maintenance on species of special concern such as Eastern hellbender, freshwater mussels (including green floater and pistolgrip), and New River crayfish.
- Adequacy of the existing ramping rate to prevent fish stranding in the Buck bypassed reach.

The Licensee does not anticipate that operation and maintenance of the Project over the new license term will have any short- or long-term, unavoidable, adverse impacts on aquatic resources.

The sub-sections that follow will be further updated in the FLA, following completion of the ongoing relicensing studies and reporting in the USR.

E.9.2.2.1 Effects of Continued Project Operation on Water Quality and Turbidity

Effects of continued and proposed Project Operations on water quality are discussed in Section E.8 of this DLA and the Water Quality Study report will be included in the USR. The results of the studies conducted for the previous relicensing support a conclusion that due to the small size and short retention time of the Project reservoirs, the lack of thermal stratification in the reservoirs, and the run-of-river operation of the Project, the Project does not affect ambient water quality (i.e., water temperature and DO levels) in this reach of the upper New River during normal project operations.

As previously summarized in this document, Appalachian is presently conducting study to evaluate the potential impact that Project operations, in particular drag rake operations, have on turbidity concentrations in the Project tailraces. Results from the turbidity study will be provided in the FLA.

E.9.2.2.2 Minimum Flows for Protection of Aquatic Resources (Byllesby)

Discussion will be provided in the FLA, following completion of the ongoing Bypass Reach Flow and Aquatic Habitat Study.

E.9.2.2.3 Potential Need for Minimum Flows for Protection of Aquatic Resources (Buck)

Discussion will be provided in the FLA, following completion of the ongoing Bypass Reach Flow and Aquatic Habitat Study.

E.9.2.2.4 Effects of Continued Project Operation on Entrainment and Impingement of Resident Fishes

To date, the findings of the current study concur with the historical entrainment study (Appalachian 1991b) completed for the prior relicensing in that effects to the fish community in the Project vicinity are expected to be minimal. Most fish would not be excluded by the intake trashracks at Byllesby and Buck intake structures; however, velocities in front of the intakes are comparable to normal flow conditions of the New River and would therefore likely be navigable by most juvenile and adult fish in the area. While the greatest opportunity for fish mortality at a facility is associated with potential contact with the turbine runner blades, injuries and mortalities can result from other mechanisms including extreme pressure changes, shear stress, water turbulence, cavitation, and grinding (Deng et al. 2005); however, the historical study (Appalachian 1991b) determined that these factors are minimal at the Project. Since no significant changes have occurred at the facility that would change these parameters since the last relicensing, injuries and mortalities caused by factors other than turbine strikes are expected to be negligible. Susceptibility to entrainment is variable depending on species and time period, however most target species and species groups have low entrainment potential for most of the year. Entrainment of early life stage fishes (eggs and larvae) is likely minimal given the life history characteristics of species in the vicinity of the Project.

E.9.2.2.5 Effects of Continued Project Operation on Species of Special Concern

New River Crayfish

The Spiny Stream Crayfish was collected upstream of Byllesby Dam, while Spiny Stream Crayfish and Conhoway Crayfish were both collected between Byllesby and Buck dams, as well as downstream of Buck Dam. There were no crayfish captured at the two quantitative sites upstream of Byllesby Dam, while both species of crayfish were captured at both quantitative sites below Buck Dam, even though all four sites exhibited similar substrate, habitat composition, and physiochemical parameters.

Conhoway Crayfish were observed under large boulders near the bank and in the channel, while the Spiny Stream Crayfish were concentrated within cobble substrates and near shore cover. Overall, the presence of these two relatively abundant native crayfish species and the absence of invasive crayfish species in the Project vicinity may indicate a healthy community.

Mussels

Existing relevant and reasonably available studies of mussels within the Project area were reviewed and compared to results of summer 2020 field surveys. In total, data from six other mussel surveys conducted within the Project area between 1997 and 2018 were compiled to form a more comprehensive understanding of the mussel community in the vicinity of Project operations. Six species were observed within the Project area: purple wartyback, spike, pistolgrip, wavyrayed lampmussel, green floater, and pocketbook. Survey sites downstream of Buck Dam (downstream of the confluence of the tailrace and bypass channel) supported the highest density mussel habitats. Purple wartyback and pistolgrip were the most abundant species and mussel size data suggests that recent recruitment has occurred for these species. Results of 2020 field surveys are consistent with findings of historical surveys. High quality mussel habitat within the Project area is limited and does not support a diverse or abundant mussel community. Therefore, continued operation of the Project is not anticipated to have an effect on the mussel community of the New River within the Project area.

Eastern Hellbender

No Eastern hellbender surveys were required by FERC's SPD or performed during the Project field studies in 2020 or 2021. In the RSP, Appalachian noted that due to challenges with implementing the currently acceptable survey methodology (i.e., surveys at night, requiring lifting of large boulders, safety concerns, and potential for specimen injury or damage to habitat), Appalachian has assumed that Eastern hellbender are likely present within the Project boundary in lieu of performing a field study. In discussions at the PSP meeting and in comments filed on the PSP, VDWR, and USFWS were agreeable with this approach. While this species may occur in faster flowing sections within the general Project Boundary, the bypass reaches do not contain suitable habitat (i.e., absence of woody debris and logs) and therefore no effect of Project operations on this species is anticipated.

Dragonflies

Although larval dragonflies were collected during the field sampling efforts, no pygmy snaketail or moustached clubtail dragonfly larvae or adults were collected during the 2020-2021 Project macroinvertebrate study.

E.9.2.2.6 Adequacy of Ramping Rate to Prevent Fish Stranding (Buck Development)

Periodic or intermittent release of flows over the spillways through the Tainter gates, crest gates, flashboards, or sluice gates creates the potential for fish stranding in pockets of water in the rough substrate of the bypass reaches. Flow releases over the main spillways into the bypass reaches are generally infrequent at the Project, though more common during the wet months of November-December and February-April, and necessary during plant outages. As previously noted, replacement of sections of wooden flashboards with inflatable Obermeyer crest gates at both developments is expected to reduce inadvertent flow into the bypass reach that may potentially attract and expose fish to stranding.

For times when flows are required to be released over the main spillway, ramping rates and associated procedures (i.e., incremental gate openings and closings) are in place at each development to mitigate, as feasible, fish stranding due to spillway gate operations. During the previous licensing, FERC noted that that the Buck bypass reach is characterized by exposed bedrock and that the Commission had no evidence that this reach provided any unique or outstanding characteristics of fish habitat relative to nearby reaches. Additionally, no minimum flows were proposed by Appalachian or recommended by resource agencies during the previous relicensing.

As a condition of the existing license, Appalachian conducted a ramping rate assessment in 1997 to assess the effectiveness of the ramping procedures for the protection of the fisheries downstream of the Buck spillway. Observations, including backpack electrofishing, of representative pools were conducted following three spill events during the period March through May 1997. The first assessment (March 12, 1997) resulted in the collection of 185 fish representing 16 species. The majority of the fish appeared to be permanent residents of the larger pools in the bypass. These particular pools are maintained year-round by leakage through the flashboards and/or subsurface flow. A second assessment (March 18-19, 1997) resulted in the collection of 348 fish representing 20 species. Similar to the first assessment, almost all of the fish collected were likely full-time residents of the bypass reach. A few large Common Carp, White Suckers, and Northern Hogsuckers were identified and likely migrants. The third assessment (May 2-3, 1997) resulted in the collection of 201 fish representing 16 species. Species identified were similar to the first two assessments, but with an increased presence of larger fish such as Common Carp and Northern Hogsucker that were likely not resident to the bypass reach (Appalachian 1997).

The ramping rate assessment concluded that fish stranding is not a significant problem below the Buck spillway when the ramping procedures are followed in accordance with Article 406. The majority of the fish collected (85-90%) appeared to be permanent residents of the bypass area in pools or flowing-water areas fed by leakage through the flashboards, rain events, and possibly subsurface flow. Very

few spring-migrating fish and almost no large game fish were observed in a stranded location following any of the three spill events. Additionally, in many areas of the bypass, particularly the area within 1,600 ft of the dam, leakage and other flows continue to provide an escape route to fish species when the gates are closed. Local observers also indicated that fish that moved into the area during spill events largely departed during the final period of spill at a 1.0-ft gate opening (Appalachian 1997). On March 27, 1998, FERC approved Appalachian's ramping rate assessment report, inclusive of and recommendations for Appalachian to continue to retain the ramping rate protocol assessed in the 1997 study. Additionally, as described above, Appalachian expects that continued operation of the Project with the inflatable Obermeyer crest gates installed at each dam will reduce instances of spills to the bypass reach that may not conform to the ramping rate required for the spillway gate operations.

E.9.3 Protection, Mitigation, and Enhancement Measures Proposed by the Applicant, Resource Agencies, and/or Other Consulting Parties

Appalachian proposes to continue to operate the Project in the existing run-of-river mode for the protection of multiple resources.

For the protection of mussels, Appalachian will continue to consult with USFWS and VDWR in advance of reservoir drawdowns as required for periodic scheduled or unscheduled Project maintenance and conduct mussel salvage surveys as appropriate.

For the protection of fishery and aquatic resources in the Buck bypass reach, Appalachian proposes to continue to operate the Project with the existing ramping rate. If final results of and additional consultation associated with the ongoing Bypass Reach Flow and Aquatic Habitat Study suggest that modifications to the existing ramping rate is appropriate, this measure will be included as part of Appalachian's proposal in the FLA. Agency comments during consultation identified concerns with the ramping rate of spills and the potential for stranding of spring spawning Walleye in the far left channel (facing downstream) of the Buck bypass reach. Appalachian will evaluate potential modifications for the provision or ramping of spills to the Buck bypass reach during Walleye spawning season, in consultation with relicensing participants through the USR process. Such measures may be proposed in the FLA and/or recommended by agencies. Appalachian will update this section in the FLA to reflect the findings and recommendations of the ongoing Aquatic Resources studies.

E.10 Wetlands, Riparian, and Littoral Habitat

E.10.1 Affected Environment

E.10.1.1 Overview

Wetlands are generally defined as those areas that are inundated or saturated by surface or ground water at a frequency and duration sufficient to support vegetation typically adapted for life in saturate soil conditions. The USACE and VDEQ have jurisdiction over wetlands in Virginia.

The littoral zone, in the context of a large river system, is the habitat between about a half-meter of depth and the depth of light penetration (Wetzel 1975). The littoral width varies based on the geomorphology and rate of sedimentation of the stretch of river (Wetzel 1983).

Riparian habitats are areas that support vegetation found along waterways such as lakes, reservoirs, rivers, and streams. The boundary of the riparian area and the adjoining uplands is gradual and not always well defined. However, riparian areas differ from the uplands because of their high levels of soil moisture, frequency of flooding, ability to provide important ecosystem functions, and unique assemblage of plant and animal communities (Virginia State University 2000; Mitsch and Gosselink 2000). Riparian habitat in the Project area is dominated by hardwood forest. Small areas of open field or cleared areas are present along parts of the western and eastern shorelines of the New River, including electric transmission corridors in the vicinity of the Project.

E.10.1.2 Existing Data and Previous Studies

E.10.1.2.1 Wetland, Riparian Zone, and Littoral Maps and Acreage

Wetland, riparian, and littoral habitats within the Project boundary are associated with the margin and near-shore areas of the impoundments. The USFWS National Wetlands Inventory (NWI) data and digital orthophotography of the Project area identifies the vegetated wetlands within the Project boundary as consisting of areas of aquatic beds in the impoundment, palustrine emergent wetlands along the edge of the river channel and palustrine forested wetlands along the upper New River. Sediment deposition in the backwater areas of the project reservoirs has created sites suitable for wetland vegetation, including about 27 acres of emergent wetland vegetation bordering the Byllesby impoundment and about 15 acres bordering the Buck impoundment (Appalachian 1991a). Additional wetlands are also created by sediment deposition at other areas, such as a small area approximately 100 yards upstream of the gated spillway dam at the Buck Development.

A map of wetland habitats existing in the Project vicinity is presented in Figure E.10-1. Table E.10-1 defines the NWI classification system associated with the wetlands maps (USFWS Undated) and provides

the available acreage of each classification of wetlands within the Project vicinity. The NWI wetlands in the vicinity of the Project encompass approximately 9.17 acres.

Table E.10-1. National Wetlands Inventory Classification System and Estimated Acreage

Wetlands Code	System	Class	Subclass	Regime	Estimated Acres
PEM1C	Palustrine	Emergent	Persistent	Seasonally flooded	5.89
PFO1C	Palustrine	Forested	Persistent	Seasonally flooded	0.21
PUSC	Palustrine	Unconsolidated Shore	-	Seasonally flooded	3.07

The approximately 6-acre emergent wetland listed in Table E.10-1 is the Byllesby wetland, created as mitigation for dredging conducted at the Project in 1997. This wetland is located approximately 500 ft upstream of the Byllesby Dam. Wetland vegetation at this location is at an elevation higher than the normal reservoir operating level.

Based on the NWI maps, site observations, and review of aerial photography of the Project area, some potential littoral habitats for wildlife (such as frogs, turtles, and wading birds) have been identified in three locations: the area associated with the exposed bedrock below the Byllesby Development; near the confluence of Crooked Creek; and the southern extent of the Project boundary below Chestnut Creek.

For the purposes of this section, the term “riparian” shall be used to refer to anything connected or immediately adjacent to the shoreline or bank of the New River, Crooked Creek, or Chestnut Creek. Although the term “riparian buffer” generally refers to the naturally vegetated shoreline, floodplain, or upland forest adjacent to a surface water body, the quantification of riparian habitat requires the calculation of a buffer size from which to base the amount of riparian habitat located within a specified area. The Virginia Department of Conservation and Recreation Riparian Buffers Modification and Mitigation Guidance Manual (VDCR 2006) suggests a 100-ft buffer in order to effectively slow down runoff, prevent erosion, and to filter non-point source pollution from runoff. The riparian zone serves as the primary interface between riverine and upland habitats, influencing both the primary productivity and food resources within the river. The majority of riparian habitat within the Project boundary is located within the Deciduous Forest, Mixed Forest, and Developed, Low-Intensity cover types. Lands associated with the Byllesby Development include about 32 acres of riparian forest, including silver maple, black willow, and sycamore with understory riparian herbaceous species (Appalachian 1991a). Table E.2-2 in Section E.2 lists the estimated land use acreage within the Project boundary.

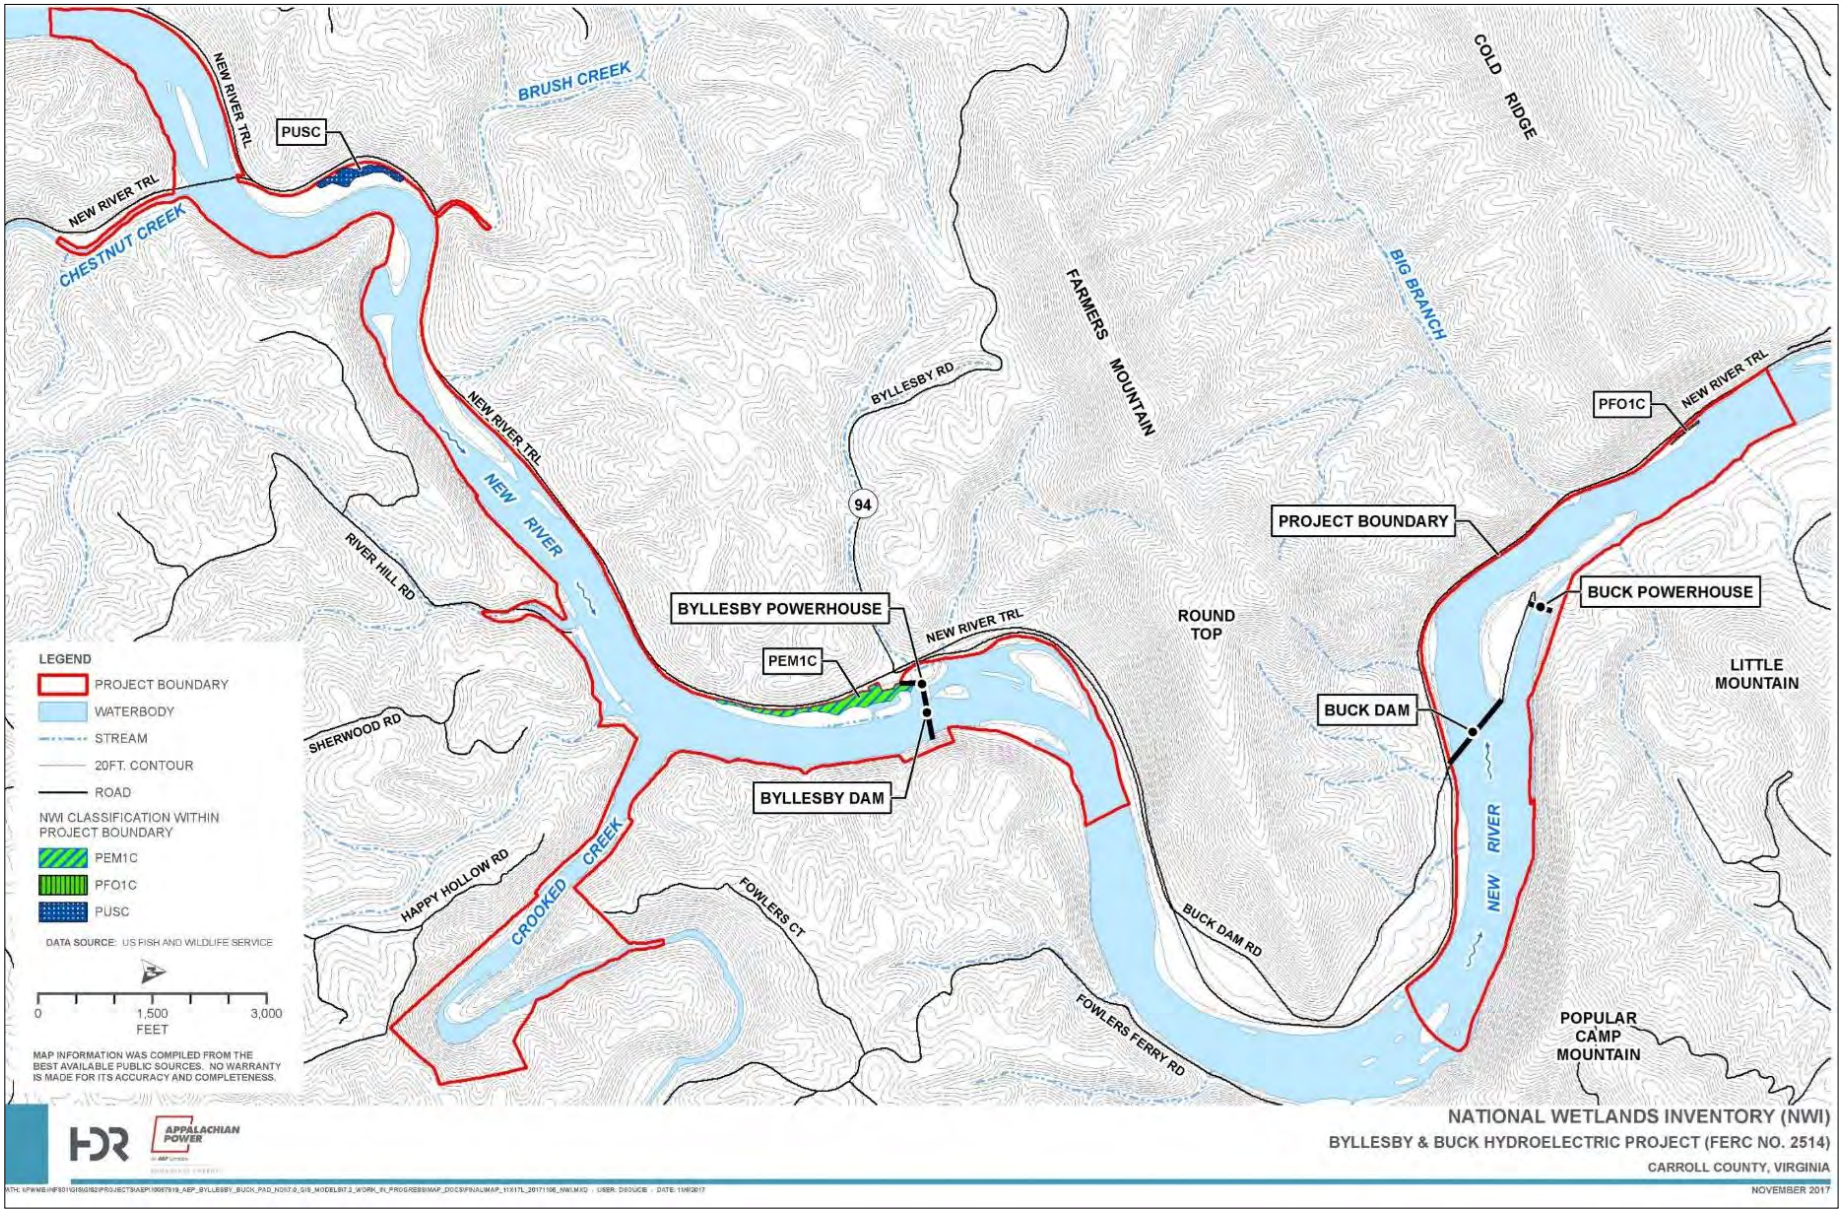

Figure E.10-1. NWI Wetlands in the Vicinity of the Project

E.10.1.2.2 Wetland and Riparian Vegetation

The species composition of the approximately 6-acre wetland upstream of the Byllesby Dam (Figure E.10-2) has been more recently documented through transect monitoring of this wetland that occurred over 2004-2007. The dominant species observed at this wetland in 2007 are listed in Table E.10-2. Species noted with an "*" were also noted as present (at the genus level) at wetlands within the larger Project boundary during the 1990 survey conducted by Appalachian (Appalachian 1991a). Additional emergent wetland vegetation observed during the 1990 survey included water plantain (*Alisma* sp.), swamp milkweed (*Asclepia incarnata),* red willow dogwood *(Cornum amomum*), Joe-pye-weed (*Eupatorim* sp.), witch hazel (*Hamamelis virginia*), cardinal flower (*Lobelia cardinalis*), monkey flower (*Mimulus* sp.), green cone flower (*Rudbeckia* sp.), black willow, cord grass (*Spartina* sp.), and vervain (*Verbena* sp.).

Figure E.10-2. Representative Photograph of Byllesby Wetland (Photo from 2007)

Table E.10-2. 2007 Byllesby Wetland Vegetation Survey Species List

Common Name	Scientific Name	Indicator Status[1]
False nettle (bog hemp)	*Boehmeria cylindrica*	FACW+
Rough (or American) barnyard grass	*Echinochloa muricata*	FACW+
Orange (or common or spotted) jewelweed or touch-me-not	*Impatiens capensis**	FACW
Common (or soft) rush	*Juncus effuses**	FACW+
Cut-grass	*Leersia oryzoides*	OBL
Reed canary grass	*Phalaris arundinacea*	FACW+
Dotted smartweed (or knotweed)	*Polygonum punctatum**	OBL
American (or arrowleaf) tearthumb	*Polygonum sagittatum**	OBL
Broadleaf arrowhead	*Sagittaria latifolia**	OBL
Woolgrass	*Scirpus cyperinus**	FACW+
Bur-reed	*Sparganium* spp.	OBL
Woolgrass	*Typha latifolia**	OBL
Wingstem	*Verbesina alternifolia*	FAC

[1] obligate wetland (OBL), facultative wetland (FACW), facultative (FAC).

A detailed habitat assessment in the vicinity of the Project was conducted for Appalachian in April 2017 and submitted to USFWS and VDCR in July 2017, as part of a habitat assessment for Virginia spiraea (*Spiraea virginiana*) in support of the license amendment application for installation of the inflatable Obermeyer crest gates. The survey area was evaluated via a combination of desktop assessment, field-based habitat assessments, and presence/absence surveys within identified suitable habitat and encompassed approximately 12 miles along the New River between Fries Dam and the portion of the New River just downstream of Buck Dam. The survey area also included tributaries along this span, where suitable Virginia spiraea habitat was identified. A total of 102 separate habitat patches were delineated within the survey area.

The riparian plant Virginia spiraea, which is federally listed as threatened, is of interest for the Project, as this species is known or believed to occur in Carroll County, Virginia. Virginia spirea may have potentially occurred upstream of the Byllesby Dam historically, however, there has been no documentation or verification of its presence or exact location. There are no verified records of this species occurring in or adjacent to the Project boundary.

The majority (84) of the habitat patches delineated during the above-referenced 2017 habitat assessment did not contain any habitat suitable to support Virginia spiraea. Ten patches were found

to provide low-suitability habitat, and eight patches were found to provide moderate-suitability habitat. No instances of Virginia spiraea were, however, observed in any of these patches.

E.10.1.2.3 Invasive Aquatic Plants

There are close to 100 invasive plant species in Virginia (VDCR 2017a). Hydrilla (*Hydrilla verticillata*), curly-leaf pondweed (*Potamogeton crispus*), and brittle naiad (*Najas minor*) have been previously documented in the New River in Claytor Lake (Normandeau 2008). Hydrilla is a perennial herb that is found in a variety of aquatic environments. It spreads through dispersal of plant fragments. It grows aggressively and spreads through shallower areas forming thick mats in surface waters, which block sunlight to native plants below. This species has been shown to displace native vegetation and significantly alters the physical and chemical characteristics of waterbodies. In Virginia, it was first reported in 1982 in the Potomac River and is now present in waters throughout the state. Triploid Grass Carp (*Ctenopharyngodon idella)* have been stocked in the upper New River by VDWR to control Hydrilla in Claytor Lake with great success (Weberg et al. 2015).

An aquatic plant community study was conducted in 2012 on the reach of the upper New River between Buck Dam and the head of Claytor Lake to evaluate the success of the Grass Carp stockings. The reach was visually surveyed from canoe, utilizing a double-sided rake attached to a rope to monitor for plant presence in deeper pool sections. To gauge the occurrence and abundance of aquatic-plant species, a single 5-minute drift-net sample using a seine was done every 5 river kilometers. Drift samples were also collected by wading into the river at each sampling site. The study resulted in identification of 13 macrophyte species, including one Virginia-listed aquatic invasive plant, curly-leaf pondweed, discussed in further detail below. No hydrilla was observed in the 2012 survey (Weberg et al 2015).

Curly-leaf pondweed grows entirely as a submersed aquatic plant with no floating leaves. It can survive and grow at very low light levels and low water temperatures (USGS 2016). As a result, it often thrives in polluted waters with low light penetration. It can survive under the ice throughout the winter and exhibit rapid growth in the spring when water temperatures rise above 10°C. It can outcompete native species for light and space early in the growing season, which can reduce plant diversity and alter predator/prey relationships. Large infestations can impede water flow and cause stagnant water conditions (USGS 2016).

Brittle naiad is an annual submersed rooted or floating plant. It prefers stagnant or slow-moving waters such as ponds, lakes, reservoirs, and canals. It can grow in depths of up to four meters and is tolerant of turbidity and eutrophic conditions. It reproduces by fragmentation and by one-seeded fruits. It starts growing early in the season and blocks sunlight from native species, thereby inhibiting their growth. It

can also form dense underwater meshes, which can produce unfavorable conditions for aquatic organisms (NOAA 2017).

E.10.1.2.4 Wetlands and Riparian Wildlife

Information on specific wildlife known to occur in wetland and riparian habitats in the Project vicinity is not available. However, many species likely to occur within the Project vicinity typically use wetland or riparian habitats at some point in their lives. Many of the species mentioned above may utilize riverine and lacustrine habitat within the Project boundary for permanent, temporary, or transient uses.

E.10.2 Environmental Analysis

E.10.2.1 Studies in Support of the Current Relicensing

In support of the current relicensing, Appalachian conducted a Wetlands, Riparian, and Littoral Habitat Characterization Study in 2021. The goal of the Wetlands, Riparian, and Littoral Habitat Characterization Study is to identify and characterize the existing wetlands, waterbodies, and riparian and littoral vegetative habitats (including emergent and submerged aquatic vegetation beds) in the Study Area. Specific study goals and objectives include the following:

- Perform a desktop characterization using the USFWS National Wetlands Inventory (NWI), the Wetland Condition Assessment Tool (WetCAT) (VDEQ 2019), and other resources such as GIS-based topographic maps, hydrography, aerial imagery, and soil surveys to identify and describe, approximate, and classify wetlands and waterbodies (i.e., streams, creeks, rivers) within the Study Area (including upland, littoral, and riparian zones of the Study Area);
- Perform a field verification survey to confirm the location, dominant vegetative community and vegetation classification identified in the desktop survey and resulting maps;
- The field verification will include identification of littoral and instream vegetation in the Study Area to characterize the availability of littoral, submerged, and emergent vegetative habitat;
- Using the results of the desktop characterization and field verification, develop a GIS-based map identifying wetlands, waterbodies, and riparian, littoral, and instream vegetative community composition according to the Cowardin Classification System (Cowardin et al. 1979). The map will also identify the location and species of any invasive aquatic vegetation identified in the literature review or during the field verification efforts; and
- Using the results of the desktop and field verification efforts, evaluate the potential for Project effects on wetlands, riparian, and littoral habitat in the Study Area.

The Wetlands, Riparian, and Littoral Habitat Characterization study was carried out as a desktop analysis followed by field verification of streams and wetlands within the study area. The study will provide adequate information to assess potential Project operations-related effects to wetlands, riparian, and littoral habitats in the Study Area.

Reporting from this study is ongoing, and detailed final results will be presented in the USR and summarized in the FLA.

E.10.2.2 Project Impacts on Wetlands, Riparian, and Littoral Habitat

In SD3, FERC staff identified the following resource issue to be evaluated in its NEPA document:

- Effects of continued project operation and maintenance, on riparian and wetland habitat, emergent and submerged aquatic vegetation beds (including hornleaf riverweed and water willow), and associated wildlife.

Periodic drawdowns of the impoundment for Project maintenance have the potential to temporarily dewater wetland, riparian, or littoral areas, though for short-duration drawdowns, soils are likely to remain saturated between inundation periods. Longer-term drawdowns could potentially cause soils in wetland areas to lose saturation, resulting in temporary loss of wetland vegetation. This potential Project impact has been previously studied at the Byllesby wetland. Following completion of maintenance activities at Byllesby Dam in 2005-2006 that required a drawdown of the impoundment by approximately 11 ft, Appalachian conducted monitoring of the plant community in an adjacent wetland that was created by deposition of dredged material in shallow water during 1997, pursuant to a VWP Permit. Monitoring of the plant community was performed each year from 2004 through 2007. Despite the lower water levels during two growing seasons during this period, no appreciable change in the extent or composition of the wetland plant community occurred.

Sediment accumulation is known to be slowly occurring at locations within and around the impoundments, in some cases leading to the creation of new wetland areas. If such areas interfere with Project operations, there could be a need in the future to dredge such areas, such as was done during 1997 and 2014. Adverse effects of this activity would be addressed through the protections and mitigations required by approvals and permits to be issued by USACE and VDEQ and FERC standard license articles.

The Licensee does not anticipate that operation and maintenance of the Project over the new license term will have any short- or long-term, unavoidable, adverse impacts on wetland, riparian, and littoral resources.

E.10.3 Protection, Mitigation, and Enhancement Measures Proposed by the Applicant, Resource Agencies, and/or Other Consulting Parties

Wetland, riparian, and littoral habitats at the Project are reflective of current Project operations. Appalachian proposes to maintain the run-of-river mode of operation for each development and existing measures and programs to protect wildlife habitat. Appalachian does not expect that operation of the Project as presently proposed over the term of the new license to adversely impact wetland, littoral, and riparian habitat, and notes that Appalachian's rights, and FERC's jurisdiction over, such lands within the Project boundary provide a level of additional regulatory protection for these resources.

While the existing WMP has provided a general means for qualitatively monitoring land development and general wetland, littoral, and riparian habitat conditions over the term of the existing license, Appalachian does not believe that the process has yielded meaningful information or been necessary to inform decisions or manage lands within the Project Boundary. Appalachian does not propose to continue the WMP during the term of the new license.

No additional environmental PM&E measures beyond those already in place at the Project are presently proposed by Appalachian.

E.11 Rare, Threatened, and Endangered Species

E.11.1 Affected Environment

E.11.1.1 Federally Listed Threatened, Endangered, and Candidate Species

A review of federally listed threatened, endangered, and candidate species using the USFWS IPaC online system was conducted on December 18, 2018 for both the Byllesby and Buck Project boundaries. Based on the IPaC review, a total of three threatened, endangered, or candidate species have the potential to occur within the Project boundary (Table E.11-1).

Table E.11-1. Federally Listed Species Potentially Occurring within the Project Boundary

Common Name	Scientific Name	Status	Byllesby Development	Buck Development
Indiana bat	*Myotis sodalis*	Endangered	X	X
Northern long-eared bat	*Myotis septentrionalis*	Threatened	X	X
Virginia spiraea	*Spiraea virginiana*	Threatened	X	

Source: USFWS 2018c

Additionally, on November 21, 2018, the Candy Darter was listed as endangered under the Endangered Species Act with proposed designated critical habitat, effective December 21, 2018 (USFWS 2018a). Although, watersheds of five tributaries to the New River are listed as Candy Darter critical habitat, the nearest critical habitat to the Project is the Cripple Creek tributary, which confluences with the New River approximately 5 river miles downstream of Buck Dam. (See also discussion in Section E.9.1.5.1.)

The green floater was included in an April 2010 petition for listing of 404 southeastern aquatic species submitted to the USFWS by the Center for Biological Diversity and is currently under review for listing. The green floater is also currently listed as threatened in Virginia (VDWR 2021). The USFWS is expected to complete their evaluation and peer review process by the end of 2021, and a federal listing determination for the green floater would then follow (USFWS 2021b). A single live green floater was collected from the impoundment above Byllesby Dam during mussel salvage and relocation activities performed from April 30 to May 1, 2018 during a planned reservoir drawdown for the Obermeyer gate replacement at Byllesby Dam (Stantec 2018a). (See also discussion in Section E.9.1.5.2.)

E.11.1.1.1 Indiana Bat

Indiana bats are found over most of the eastern half of the United States (USFWS 2016). The Indiana bat is a relatively small, dark-brown bat. Although they only weigh around one-quarter of an ounce, they have a wingspan of 9 to 11 inches (USFWS 2016).

Indiana bats hibernate during winter in caves or occasionally in abandoned mines. They hibernate in cool, humid caves with stable temperatures under 10°C but above freezing. Very few caves are known to have these characteristics. After hibernation, Indiana bats migrate, often long distances, to their summer habitat in wooded areas where they roost under loose tree bark on dead or dying trees. They forage in or along the edges of forested areas (USFWS 2016). Migratory females may migrate up to 357 miles to form (summer) maternity colonies to bear and raise their young, with each giving birth to just a single pup (USFWS 2016). Both males and females return to hibernacula in late summer or early fall. Indiana bats mate during the fall before they enter hibernation, but fertilization is delayed until the spring after they emerge from the caves (USFWS 2007a).

Indiana bats are found over most of the eastern half of the United States. Critical habitat for this species designated by USFWS includes 11 caves and two abandoned mines in Illinois, Indiana, Kentucky, Missouri, Tennessee, and West Virginia. During winter, Indiana bats are restricted to suitable underground hibernacula. The vast majority of these sites are caves located in karst areas of the east-central U.S.; however, Indiana bats also hibernate in other cave-like locations, including abandoned mines. No critical habitat is designated within the Project boundary. Hellhole Cave in Pendleton County, West Virginia, northeast of the Project, is a Priority 1 (≥ 10,000 bats) hibernacula and is designated as critical habitat for the Indiana bat.

In summer, most reproductive Indiana bat females occupy roost sites under the exfoliating bark of dead trees that retain large, thick slabs of peeling bark. Primary roosts usually receive direct sunlight for more than half the day. Roost trees are typically within canopy gaps in a forest, in a fence line, or along a wooded edge. Habitats in which maternity roosts occur include riparian zones, bottomland and floodplain habitats, wooded wetlands, and upland communities. Indiana bats typically forage in semi-open to closed (open understory) forested habitats, forest edges, and riparian areas (USFWS 2007a). Habitat suitable for Indiana bat foraging and roosting is likely available within the Project boundary.

Multiple biological opinions have been developed for the Indiana bat (USFWS 2017a). A draft recovery plan was issued for the Indiana bat in April 2007 (USFWS 2007a). No official status reports exist for the Indiana bat; however, the general status of this species, the associated listing, fact sheets, range maps, and other important information are available on the USFWS website.

E.11.1.1.2 Northern Long-Eared Bat

The northern long-eared bat is found across much of eastern and north-central United States and all Canadian provinces from the Atlantic Ocean west to the southern Yukon Territory and British Columbia (USFWS 2013). It is a medium-sized bat, measuring 3.0 to 3.7 inches, with a wingspan of 9 or 10

inches. Its fur color can be medium to dark brown on the back and tawny to pale brown on the underside. The bat is distinguished by its longer ears relative to other bats in the genus Myotis.

The northern long-eared bat spends winters hibernating in caves and mines, preferring hibernacula with very high humidity. During the summer months, the northern long-eared bat prefers to roost singly or in colonies underneath bark, in cavities, or in the crevices of live or dead trees (USFWS 2013; USFWS 2015b). Breeding begins in late summer or early fall when males swarm near hibernacula. After a delayed fertilization, pregnant females migrate to summer colonies where they roost and give birth to a single pup. Young bats start flying 18 to 21 days after birth, and adult northern long-eared bats can live up to 19 years (USFWS 2013).

Northern long-eared bats emerge at dusk and fly through the understory of forested hillsides feeding on moths, flies, leafhoppers, caddisflies, and beetles. They also feed by gleaning motionless insects from vegetation and water (USFWS 2013).

The most severe and immediate threat to the northern long-eared bat is white-nose syndrome. As a result of this disease, numbers have declined by 99 percent in the northeast. Other significant sources of mortality include impacts to hibernacula from human disturbance. Loss or degradation of summer habitat as a result of highway or commercial development, timber management, surface mining, and wind facility construction and operation can also contribute to mortality (USFWS 2013).

The spatial distribution for the northern long-eared bat extends from Montana and Wyoming in the west, south to eastern Texas, across the northern portions of Mississippi, Alabama, Georgia, and North Carolina, north to Maine, and across the Great Lakes. As this species overwinters in local or regional hibernacula, it does not migrate extensive distances and, therefore, does not have significant temporal distribution (USFWS 2013). No critical habitat has yet been determined or designated by USFWS for this species.

Multiple biological opinions have been developed for the northern long-eared bat (USFWS 2017b). No official status reports exist for the northern long-eared bat; however, the general status of this species, the associated listing, fact sheets, range maps, and other important information are available on the USFWS website. A recovery plan has not yet been developed for the northern long-eared bat.

E.11.1.1.3 Virginia Spiraea

Virginia spiraea is a perennial shrub with many branches growing in height from 3 ft to 10 ft. The plant produces flowers that are yellowish green to pale white. The shrub blooms from May through early July, but flower production is sparse and does not begin until after the first year of establishment. Virginia spiraea occurs along rivers and streams and relies on periodic disturbances, such as high-

velocity scouring floods, which eliminate competition from trees and other woody vegetation. Virginia spiraea is a southern Appalachian species, with isolated populations found in the mountain regions of Georgia, North Carolina, Tennessee, Kentucky, Virginia, Ohio, and West Virginia. Little population expansion has been reported for this species and temporal distribution is limited. No critical habitat has been designated by USFWS for this species.

Multiple biological opinions have been developed for Virginia spiraea. No official status reports exist for Virginia spiraea; however, the general status of this species, the associated listing, fact sheets, range maps, and other important information are available on the USFWS website. A draft recovery plan was issued for Virginia spiraea in November 1992 (USFWS 1992).

Following consultation with the USFWS in support of the non-capacity license amendment application for installation of the inflatable Obermeyer crest gates at both developments, a habitat suitability assessment and a presence/absence survey for Virginia spiraea was conducted by Appalachian in 2017. The geographic scope of this survey was from Fries Dam to the downstream extent of the Project boundary for the Buck Development. No instances of Virginia spiraea were observed within any habitat patches identified as having at least low or moderate suitability for this species. The report of this survey was submitted to USFWS and USFS in July 2017.

An additional rare plant field survey was completed by Appalachian in July 2017 in support of a non-Project related transmission project in the vicinity of Buck Dam Road. Prior to the survey, USFS provided a list of 56 designated sensitive species under the National Threatened, Endangered, and Sensitive Species Program that had the potential to occur in this area, including Virginia spiraea and the federally threatened small whorled pogonia (*Isotria medeoloides*). Neither presence nor suitable habitat for either species was observed in the survey area (Figure E.11-1).

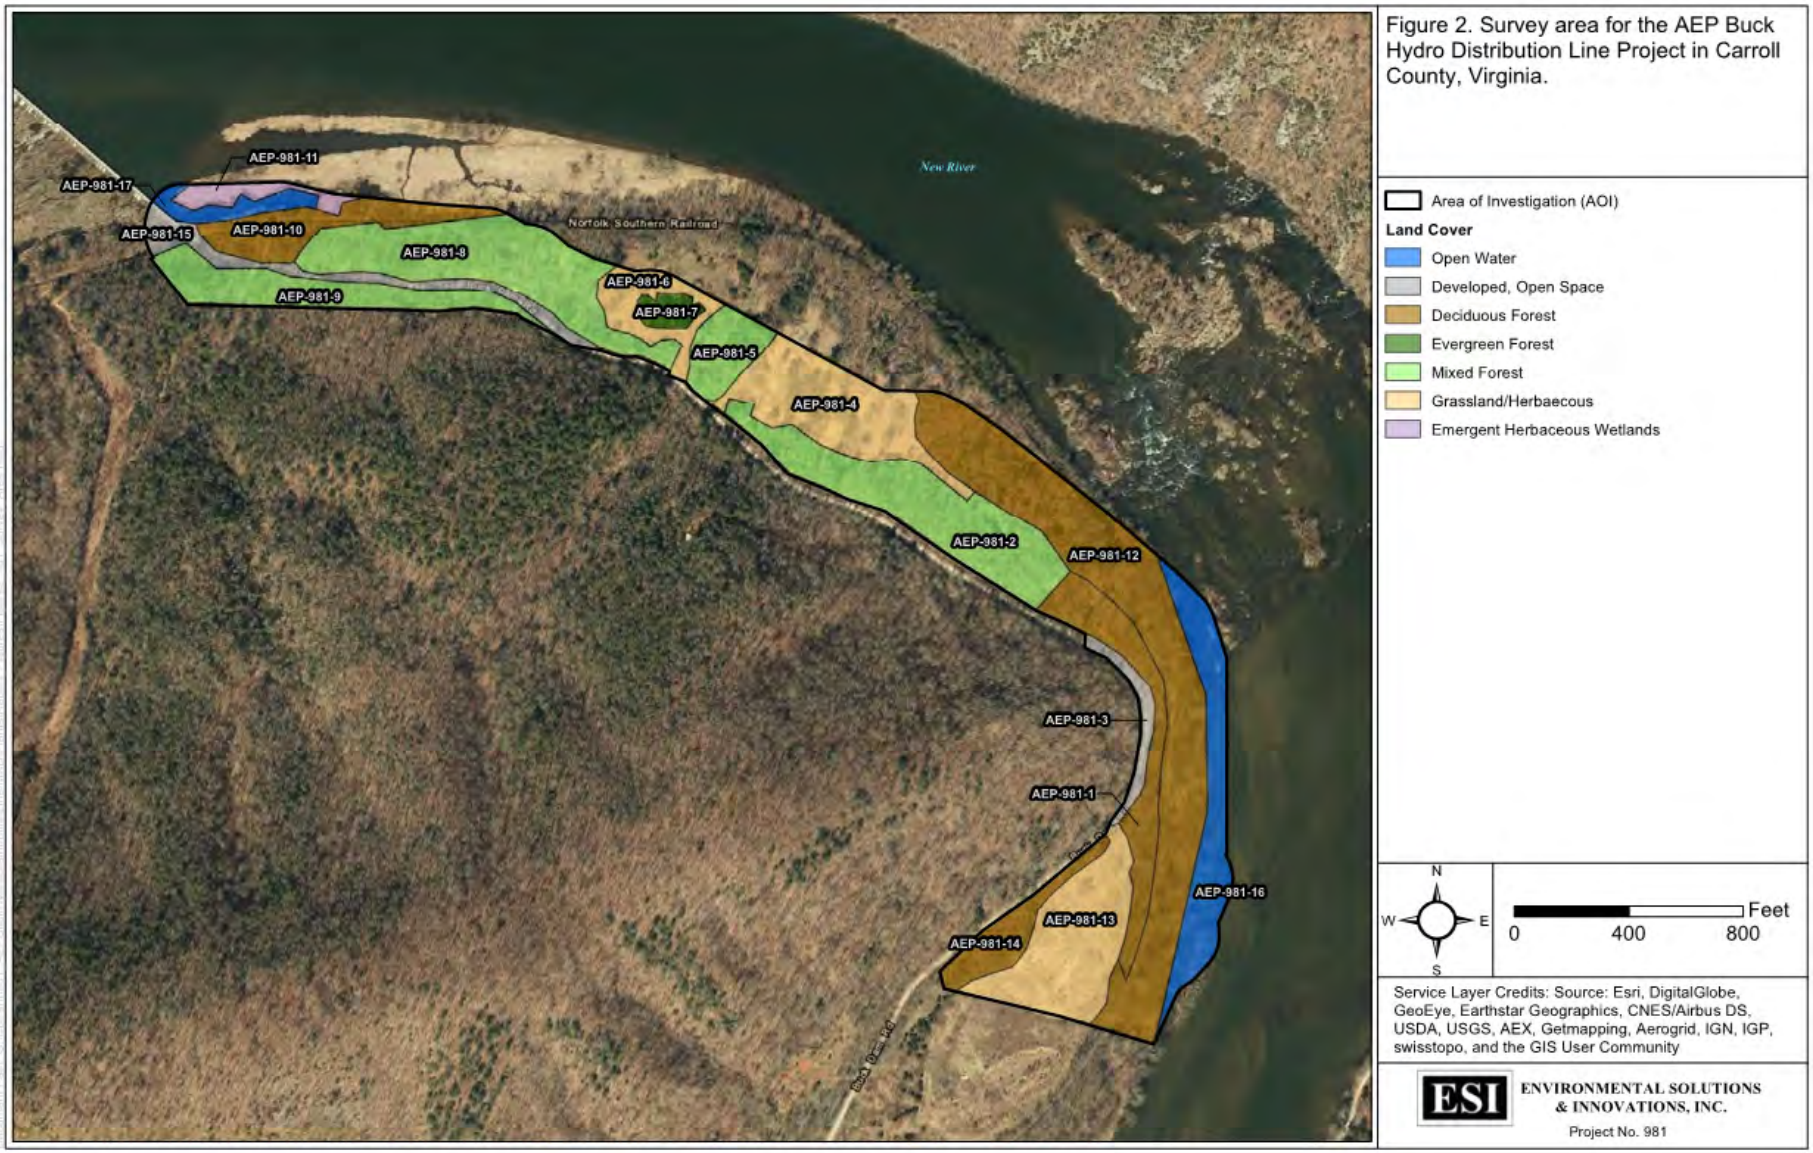

Figure E.11-1. Area Subject to Rare Plant Survey in July 2017

E.11.1.2 State-listed Threatened, Endangered, and Candidate Species

Authorized by the 1979 Endangered Plant and Insect Species Act of the Code of Virginia, the Virginia Department of Agriculture and Consumer Services, VDWR, and VDCR cooperate to provide protection for Virginia's threatened and endangered species. The Virginia Department of Agriculture and Consumer Services is the regulatory authority for the conservation and preservation of threatened and endangered plant and insect species. The VDWR has legal authority for preservation of vertebrate and other invertebrate endangered and threatened species. The VDCR Division of Natural Heritage produces an inventory of the Virginia's natural resources and maintains a database of ecologically significant areas.

By letter dated September 23, 2017, the VDCR identified two species of concern within the Project vicinity, the moustached clubtail and the pygmy snaketail, and provided information on these species, summarized below.

In addition, a geographic search of the VDWR Fish and Wildlife Information Service was conducted for a 3-mile radius from each Project dam and those species with a status concern for conservation are identified in Table E.11-2. Species lists between the two developments were the same, with the exception of the elktoe, which was only identified during the search for the Byllesby Development. In addition, a search using the VDGIF Little Brown Bat and Tri-colored Bat Winter Habitat and Roosts Application indicated that both of the developments boundaries are outside of the 5.5-mile buffer zone of the closest known hibernaculum sites (VDGIF 2018b).

Table E.11-2. Rare Species with Historical Records at or within the Project Vicinity

Common Name	Scientific Name	Status*	Tier**
Amphibians			
Blue Ridge dusky salamander	*Desmognathus orestes*		IVc

[1] The Candy Darter was listed as endangered by the USFWS on November 21, 2018 (effective December 21, 2018) (USFWS 2018a).
*FE=Federal Endangered; FT=Federal Threatened; SE=State Endangered; ST=State Threatened; FP=Federal Proposed; C=Federal Candidate; CC=Collection Concern.
Virginia Wildlife Action Plan Tier Ranking:
**I=VA Wildlife Action Plan - Tier I - Critical Conservation Need. II=VA Wildlife Action Plan - Tier II - Very High Conservation Need. III=VA Wildlife Action Plan - Tier III - High Conservation Need. IV=VA Wildlife Action Plan - Tier IV - Moderate Conservation Need.
Virginia Wildlife Action Plan Conservation Opportunity Ranking:
a - On the ground management strategies/actions exist and can be feasibly implemented.
b - On the ground actions or research needs have been identified but cannot feasibly be implemented at this time.
c - No on-the-ground actions or research needs have been identified, or all identified conservation opportunities have been exhausted.

E.11.1.2.1 Odonates

The moustached clubtail dragonfly inhabits mostly rapid, clear, rocky streams and rivers and occasionally the exposed shorelines of lakes. This species is found in southeastern Canada and the northeastern portion of the United States where its range extends southward along the Appalachian Mountains, but rarely reaches into North Carolina and Georgia. In Virginia, this species is known to

occur from areas of the New River, specifically Grayson, Carroll, and Wythe counties, but it has also historically occurred in August and Bath Counties.

The pygmy snaketail dragonfly is found from northeast Maine, west to Wisconsin, and south to Virginia and Kentucky. It is found in big, clear rivers with high water quality and stable flow over coarse cobbles and periodic rapids. The larvae overwinter and take flight late April to early June. The nymph of this species occurs in fast-flowing water in sand and gravel substrates (USFWS 2015c).

Adult dragonflies are predators that typically forage in clearings with scattered trees and shrubs near the parent river. They feed on mosquitoes and other smaller flying insects. Dragonflies lay their eggs on emergent vegetation or debris along the water's edge. The larvae (nymphs) are aquatic and generally inhabit sand and gravel substrate. Nymphs are particularly vulnerable to shoreline disturbances. They are also sensitive to alterations in poor water quality, thermal fluctuations, and changes in aquatic habitat.

Five study reaches ranging from upstream to downstream of the Fries Project were surveyed for dragonfly larvae in 2016-2017 (Carey et al. 2017). At least 17 species representing 4 families were identified in all reaches except Reach 3 (bypass). Moustached clubtail was found at the upstream reach and tailwater reach, but not within the Fries Project reservoir or bypass reach. Pygmy snaketail was found in the tailwater reach and downstream reach. The Allegheny river cruiser, spine-crowned clubtail and green-faced clubtail were also identified within the Fries Project area.

No moustached clubtail or pygmy snaketail specimens were collected within the Project Boundary during the 2020-2021 macroinvertebrate sampling efforts. Based on available habitat and substrates, neither of these dragonfly species are expected to occur within the Byllesby or Buck bypass channels. As such, continued operation of the Project is not expected to impact populations of moustached clubtail or pygmy snaketail.

E.11.1.2.2 Mussels

As shown in Table E.11-2, five species of freshwater mussels considered rare in the state of Virginia have been historically documented in the Project vicinity. The VDCR also indicated that the New River has been designated by the VDWR as "Threatened and Endangered Species Waters" for the pistolgrip and recommended further coordination with the VDWR to ensure compliance with the Virginia ESA.

E.11.1.2.3 Herpetofauna

In preliminary consultation with VDWR about potential Project impacts or information needs, the potential for habitat and/or occurrences of Eastern hellbender was raised. The Eastern hellbender is

listed as a federal species of concern. In Virginia, the Eastern hellbender is listed as a species of special concern and as a Tier II species in the Virginia Wildlife Action Plan. Eastern hellbender is a large, stout-bodied, fully aquatic salamander that occupies portions of New York, Pennsylvania, Ohio, Indiana, West Virginia, Kentucky, Tennessee, Alabama, Georgia, North Carolina, and Virginia. In Virginia, Eastern hellbenders are found in the mainstem and tributaries of the New River drainage and in the Clinch, Powell, and Holston River tributaries of the upper Tennessee River. Eastern hellbenders prefer clear, fast-flowing, well-oxygenated streams and rivers. Eastern hellbenders prefer stream bottoms with many large flat boulders, logs, and debris (VDGIF 2017d). According to Carey et al. (2017), the most recent Eastern hellbender encounters in the upper New River have occurred periodically from 2013-2016 near the North Carolina border. Site assessments identified Reaches 1, 4, and 5 as containing potential suitable habitat for the Eastern hellbender, however no individuals were observed. The study also noted that although suitable substrate was found (large flat rocks in gravel and cobble substrates), water temperature was well above (77 to 88°F [25 to 31°C]) the Eastern hellbender's preference range (50 to 73°F [10 to 23°C]). Although the survey did not identify Eastern hellbenders in the vicinity of the Fries Project, an individual was incidentally captured by an angler in the Impoundment (Reach 2) in February 2018. The last recorded captures of the Eastern hellbender in the mainstem of the upper New River occurred in 2002 and 2014 over 30 RM upstream of the Fries Project.

Table E.11-2, as well as the consultation record for the relicensing of the Fries Project, indicate the potential for the bog turtle (*Clemmys [Glyptemys] muhlenbergii*) to occur within the Project vicinity. The bog turtle is listed in as threatened wherever found, except for Georgia, South Carolina, North Carolina, Tennessee, and Virginia (USFWS 2018b). However, the bog turtle's status in Virginia is "Similarity of Appearance (Threatened)". Species listed for Similarity of Appearance are not subject to Section 7 consultations by the USFWS (USFWS 2018d); however, this species has unique habitat requirements. Bog turtles occur in headwater areas where they inhabit shallow, spring-fed habitats (fens, sphagnum bogs, swamps, marshy meadows, and pastures characterized by soft, muddy bottoms) characterized by clear, cool, slow-flowing water, high humidity, and an open canopy (USFWS 2015c). A desktop review of known bog turtle sites and field observations by Carey et al. (2017) showed no populations within the Fries Project vicinity, and no potential suitable habitat with hydrologic connectivity to the study area. Similarly, it is unlikely that this species is present in the vicinity of the Project, and if specimens were to occur in headwater areas upstream of the Project vicinity.

E.11.2 Environmental Analysis

In SD3, FERC staff identified the following resource issue to be evaluated in its NEPA document:

- Effects of continued project operation and maintenance on the federally listed Indiana bat, northern long-eared bat, bog turtle, candy darter, and Virginia spiraea.

Wildlife and riparian habitats and species in the vicinity of the Project are reflective of current Project operations. Appalachian proposes to maintain the run-of-river mode of operation for each development and existing measures and programs to protect wildlife habitat. Appalachian does not expect that operation of the Project as presently proposed over the term of the new license to affect habitat for RTE species.

As noted above, suitable foraging and potential roosting habitat for bats, including the species listed above, is likely common in the Project area, which supports a range of upland, riparian, wetland, and open water habitats. The upland forested habitats used by these species are not affected by normal or proposed Project operations. While habitat with low or moderate suitability for Virginia spiraea has been identified at the Project, the species is not known to occur based on recent survey in these previously identified areas.

There are no current plans for improvements or activities at the Project that would require the clearing of trees that may provide habitat for roosting or maternity colonies for Indiana bat and northern long-eared bat. Ongoing land and facility maintenance performed by Appalachian, including vegetation management, maintenance of project structures, and recreational facility maintenance has the potential to affect terrestrial and riparian or littoral habitats for RTE species. Appalachian expects that future activities at the Project will need to be conducted in accordance with prevailing guidelines of Appalachian and the USFWS.

With respect to state-listed aquatic species, periodic drawdown of the Project impoundments has the potential to have short-term impacts on littoral and near-shore habitat. Water level fluctuations in the bypass reaches have the potential to limit habitat and habitat connectivity. As previously discussed, the existing ramping rate provides a level of protection against stranding of fish in the Buck bypass reach. During the term of the new license, these issues are expected to be mitigated by completion of installation of the Obermeyer gates, which will allow for better control of water levels and more stable water levels. Operation of the dams with the new gates is expected to reduce the risk of deviations from the allowable 1.0-ft reservoir operating band, and to reduce the frequencies of inadvertent spills to the bypass reaches and of reservoir drawdowns required to repair/replace flashboards damaged by high flow events. Additionally, Appalachian notes that due to existing topographic and substrate conditions, the existing bypass reaches are not expected to provide habitat for the aquatic species described in the section above.

Refer to Section E.9.2.2 for additional discussion of Project impacts on sensitive mussels and other aquatic species.

E.11.3 Protection, Mitigation, and Enhancement Measures Proposed by the Applicant, Resource Agencies, and/or Other Consulting Parties

No PM&E measures specific to the protection of federally listed rare, threatened, endangered, or state-listed species have been recommended by regulatory agencies or other relicensing participants, and none are presently proposed by Appalachian. Mussel monitoring activities in the vicinity of the Project are ongoing for protected species at the downstream Claytor Project (as required by the Claytor Project license). Pending the outcome of the USFWS listing decision for green floater or other candidate species, Appalachian anticipates that future species surveys or other protection measures (e.g., mussel salvage survey during reservoir drawdowns for Project maintenance) may be requested and will continue to be performed in consultation with USFWS and VDWR when regulatory approvals are needed activities that have the potential to adversely impact mussels where they are known to be present at the Project.

E.12 Terrestrial Resources

E.12.1 Affected Environment

E.12.1.1 Existing Data and Previous Studies

E.12.1.1.1 Botanical Resources

Most of the land adjacent to the Project is steep and forested. Forest cover in the vicinity of the Project is of the oak-chestnut type, although there are many bare rock exposures in the rugged terrain. There is also a noteworthy percentage of pine and other types, such as hickory, hemlock, maple, ash, birch, rhododendron, locust, and basswood. The west side of the project is bounded by the Jefferson National Forest, and the east side consists of similarly forested terrain (Appalachian 1991a). According to the EA prepared by FERC for the existing license (FERC 1994), project lands include both upland forest and riparian forest, characterized by silver maple (*Acer saccharinum*), black willow (*Salix nigra*), and American sycamore (*Platanus occidentalis*) as the primary species.

E.12.1.1.2 Invasive Terrestrial Plant Species

The VDCR (2017) maintains a list of over 100 invasive plant species found within the State and includes species that pose a threat to Virginia's forests, marshes, wetlands, and waterways. These species are ranked based on the level of threat they present to natural communities and species.

E.12.1.1.3 Wildlife

The Project area supports a number of small mammals, avifauna, reptiles, and amphibians. Over 511 species were identified as potentially occurring within a three-mile radius of the Project per a geographic search on the VDWR Fish and Wildlife Information Service (VDGIF 2017a).

E.12.1.1.4 Mammals

Mammals, including commercially and recreationally important wildlife species, that occur within the Project area include white-tailed deer (*Odocileus virginianus*), coyote (*Canis latrans*), red fox (*Vulpes vulpes*), and gray fox (*Urocyon cinereoargenteus*) (VDGIF 2017a). Other species also known to occur within the general Project area include the Eastern chipmunk (*Tamias striatus*), red squirrel (*Tamiasciurus hudsonicus*), Eastern gray squirrel (*Sciurus carolinensis*), longtail weasel (*Mustela frenata*), common mink (*Neovison vison*), American beaver (*Castor canadensis*), striped skunk (*Mephitis mephitis*), raccoon (*Procyon lotor*), woodchuck (*Marmota monax*), muskrat (*Ondatra zibethicus*), meadow vole (*Microtus pennsylvanicus*), deer mouse (*Peromyscus maniculatus*), white-footed mouse (*Peromyscus leucopus*), and Northern short-tail shrew (*Blarina brevicauda*) (VDGIF 2017a).

E.12.1.1.5 Avifauna

Birds such as the Northern cardinal (*Cardinalis cardinalis*), American crow (*Corvus brachyrhynchos*), mourning dove (*Zenaida macroura*), pileated woodpecker (*Dryocopus pileatus*), and wood duck (*Aix sponsa*) are some of the many birds known to occur in the Project area (VDGIF 2017a), along with commercially and recreationally important species such as eastern turkey (*Meleagris gallopavo*), ruffed grouse (*Bonasa umbellus*), and various waterfowl species.

Bald eagle (*Haliaeetus leucocephalus*) nesting and roosting habitat occurs in the vicinity of the Project. The bald eagle was removed from the Federal Endangered Species List on August 8, 2007 and is no longer protected under the ESA; however, bald eagles are protected under the Migratory Bird Treaty Act and the Bald and Golden Eagle Protection Act. In association with agency consultation for the recent non-capacity amendment application for installation of the Obermeyer crest gates, searches for bald eagles and/or their nests were completed in the Project vicinity in April and July 2017 on behalf of Appalachian. A single bald eagle was observed on the first day along the west bank of the New River, approximately 1.4 miles upstream of the State Road 606 Bridge. The report presenting these findings was submitted to USFWS and VDCR in July 2017. On the second day, approximately 0.2 miles from this location, two bald eagles were observed perching on rocks in the river (one bald eagle was determined to be likely the same as that observed the previous day). A single juvenile bald eagle

was observed fishing approximately 0.4 mile south of Byllesby Dam during the searches conducted in July 2017; this individual flew to a roost in a tree on the riverbank upon successfully catching a fish. No calls were heard, nor nests observed during any of these observations in 2017.

An aerial transect helicopter survey for nesting bald eagles was conducted for Appalachian in the vicinity of the Project in March 2021 by ESI in support of the AEP Byllesby-Ivanhoe 88-kV Transmission Line Retirement Project (ESI 2021). The survey area included approximately 2.5 miles of line crossing the Jefferson National Forest and approximately 1.6 miles on private lands immediately adjacent to the Jefferson National Forest, comprising 90.7 miles of flight across the survey area using standard survey design guidance set forth by the USFWS National Bald Eagle Management Guidelines. One active bald eagle nest (36.803860° -80.938881°; ID BAEA01) was observed in the survey area on the New River; the nest is approximately 0.52 miles from the transmission line corridor and approximately 0.27 miles south of the Buck Dam. An unoccupied nest was identified along the New River approximately 1.1 mile north of Buck Dam at the top of a transmission tower; however, after several fly-by attempts over two days, no birds were observed attending and the nest could potentially be an osprey nest. A third smaller stick nest was observed 2.4 river miles upstream of Byllesby Dam; however, it is not consistent with a bald eagle nest. Additionally, three individual eagles were observed within the survey area over two survey events. One was perched proximate the New River 0.7 miles northwest of the nest BAEA01, one adult eagle (female) was observed incubating at BAEA01, and a third immature bald eagle was observed hunting along the New River 0.4 miles east of the Survey Area (ESI 2021).

E.12.1.1.6 Reptiles and Amphibians

A variety of reptiles and amphibians have been known to occur in the general Project vicinity. Common species may include the snapping turtle (*Chelydra serpentine*), painted turtle (*Chrysemys picta*), eastern garter snake (*Thamnophis sirtalis*), red-spotted newt (*Notophthalmus viridescens*), American toad (*Anaxyrus americanus*), spring peeper (*Pseudacris crucifer)*, green frog (*Lithobates clamitans*), American bullfrog (*Lithobates catesbeianus*), pickerel frog (*Lithobates palustris*), and wood frog (*Lithobates sylvaticus*) (VDGIF 2017a). Based on comments filed with FERC by VDWR on the PAD for the Fries Project (VDGIF letter dated November 19, 2015), additional herpetofauna that may occur in the Project area includes two amphibians—the Blue Ridge dusky salamander (*Desmognathus orestes*) and Yonahlossee salamander (*Plethodon yonahlossee*), and four additional reptiles—woodland box turtle (*Terrapene carolina carolina*), eastern hog-nosed snake *(Heterodon platirhinos*), queen snake (*Regina septemvittata*), and common ribbonsnake (*Thamnophis sauritus sauritus)*. VDWR also noted the potential for occurrence of the Eastern hellbender *(Cryptobranchus alleganiensis alleganiensis).*

E.12.2 Environmental Analysis

E.12.2.1 Studies in Support of the Current Relicensing

In support of the current relicensing, Appalachian conducted a Terrestrial Resources Study in 2021. The specific objectives and a summary of the methods and results of the Water Quality Study are included below.

The goals and objectives of the Terrestrial Resources Study are to:

- Perform a desktop characterization of the upland vegetation types within the Project boundary and classify plant communities according to "The Natural Communities of Virginia Classification of Ecological Groups and Community Types" by the VDCR Division of Natural Heritage (VDCR 2018);
- Perform a characterization of the upland habitat types in relation to wildlife resources; and
- Develop a map of the vegetative community within the upland portions of the Study Area, identifying general location and community type. The map will also identify the location of any invasive terrestrial species identified in the Study Area based on the literature review or observed during the field verification efforts.

The Terrestrial Resources study was carried out as a desktop analysis followed by field verification of upland terrestrial habitat types within the study area. This study will assist in identifying plant species and their habitats within the Project Boundary and provide baseline information from which to evaluate the effects of continued operation and maintenance of the Project on botanical resources and wildlife habitat.

Reporting from this study is ongoing, and detailed final results will be presented in the USR and summarized in the FLA.

E.12.2.2 Project Impacts on Terrestrial Resources

In SD3, FERC staff identified the following environmental issues to be addressed in their NEPA document:

- Effects of continued project operation and maintenance on upland wildlife habitat and associated wildlife such as bald eagles.

There is limited terrestrial land within the Project boundary and no potential issues related to wildlife and botanical resources have been identified. The Project has been in operation for over 100 years, and the existing terrestrial environment has developed in response to the current and proposed Project operations.

Resource agencies and other stakeholders have not identified any potential Project-related impacts to wildlife resources within the Project area. The occurrence and distribution of wildlife resources in the Project area is generally unrelated to Project operations, and Project operations have little potential to impact wildlife resources within and bordering the Project. Short-term minimal effects from normal maintenance, temporary construction activities, and ongoing operations may temporarily impact some generalist terrestrial wildlife species, but such species would be expected to move to adjacent habitat, returning once activities are complete. No significant impacts to wildlife or botanical resources at the Project are known to be occurring or expected to occur during the term of the new license.

Effects of continued project operation on upland wildlife is limited as there is very little terrestrial uplands within the Project Vicinity. Bald eagle nesting and roosting habitat occurs in the vicinity of the Project. Continued normal Project operations are not expected to affect this species. Activities that require clearing of significant trees (e.g., development of new recreation areas) or construction that could disturb breeding, should any be required to implement the terms of the new license or for other Project-related purposes over the new license term, have the potential to affect bald eagles. The National Bald Eagle Management Guidelines developed and maintained by the USFWS (2007b) provide guidance specifically for construction or development activities.

Appalachian conducts vegetation management activities on an as-needed basis using mostly mechanical vegetation removal techniques (e.g., mowing). The degree of impact resulting from this vegetation management is minor relative to other land uses that occur in the region (e.g., agricultural practices). The effects of these routine vegetation management activities are very minor in nature, and continued operation of the Project is not expected to have an adverse impact on terrestrial resources.

The Licensee does not anticipate that operation and maintenance of the Project over the new license term will have any short- or long-term, unavoidable, adverse impacts on terrestrial resources.

E.12.3 Protection, Mitigation, and Enhancement Measures Proposed by the Applicant, Resource Agencies, and/or Other Consulting Parties

Appalachian proposes to continue to operate the Project in the existing run-of-river mode for the protection of multiple resources.

In the event significant tree clearing or construction activities associated with the Project were proposed to be undertaken in the future in support of Project operation, modifications, or development of new recreational facilities within the Project Boundary, Appalachian would consult or coordinate with USFWS and VDWR in advance of the proposed activities regarding necessary survey or protection measures for protected species, including bald eagles.

While the existing WMP has provided a general means for qualitatively monitoring land development and general terrestrial and shoreline habitat conditions over the term of the existing license, Appalachian does not believe that the process has yielded meaningful information or been necessary to inform decisions or manage limited lands within the Project Boundary. Because the occurrence and distribution of terrestrial resources in the Project area is generally unrelated to Project operations, and routine Project operations have little potential to impact terrestrial resources within and bordering the Project, and no agencies or stakeholders have expressed concerns about these resources, Appalachian does not propose to continue the WMP during the term of the new license.

E.13 Recreation and Aesthetics

E.13.1 Affected Environment

E.13.1.1.1 Recreational Resources in Vicinity of the Project

The New River is a major recreational resource in southwest Virginia. A majority of the land to the west of the Project is owned by USFS and consists of the George Washington and Jefferson National Forest. Additional outdoor recreation activities are available along the river, including the New River Trail State Park, which extends along the west shore of the Project, along the right-of-way for the former Norfolk & Western railroad. The New River Trail State Park allows recreationists to hike, horseback ride, and bicycle along the river. Of particular note along the New River in southwest Virginia is the historical Shot Tower State Park, Claytor Lake in Pulaski County, and Claytor State Park adjoining Claytor Lake providing campgrounds, cottages, a marina, and hiking trails (VDGIF 2017e).

As the New River flows through mountain scenery, craggy rock cliffs, and gorges, it provides opportunities for whitewater boating, with several major Class I-III rapids, as well as an abundance of flatwater for motor-boaters and canoeists (VDGIF 2017e). Class I, II, and III rapids (for normal flows) are present from Fries to the Byllesby reservoir for whitewater boating. Class II and III rapids (for normal flows) are present below the Buck Development (American Whitewater 2017).

Fishing in the New River is popular, as the river supports populations of just about every major freshwater game fish in Virginia, including Smallmouth Bass, Spotted Bass, Largemouth Bass, Rock Bass, Striped Bass, White Bass, hybrid striped bass, Muskellunge, Walleye, Black Crappie, Channel Catfish, Flathead Catfish, Yellow Perch, Redbreast Sunfish, and Bluegill (VDGIF 2017e).

There are no formal camping facilities within, near, or adjacent to the Project Boundary. A campground (the Thompson Campground) was formerly maintained by USFS above the New River Trail upstream between Byllesby and Buck Dams.

There are no National Scenic Byways in the immediate vicinity of the Project. The Blue Ridge Parkway is located approximately 30 miles south of the Project.

National Trails System and Wilderness Areas

The George Washington and Jefferson National Forest abuts the Project to the east and west. The George Washington and Jefferson National Forest contains nearly 1.8 million acres of public lands, representing one of the largest blocks of public land in the eastern United States. The Forest contains approximately 1,646,328 acres in Virginia, 123,384 acres in West Virginia, and 961 acres in Kentucky.

Developed recreation opportunities are offered at over 200 sites in the Forest, resulting in nearly 3 million annual recreation visits. These opportunities vary from minimally developed sites such as ten-unit picnic areas with vault toilets and hand pumps, small scenic overlooks, and small non-fee campgrounds, to highly developed recreation complexes providing swimming beaches, camping spurs with utility hookups, warm showers, and flush toilets (USFS undated a).

The George Washington and Jefferson National Forest has approximately 2,100 miles of trails open to one or more non-motorized uses (hiking, horse-riding, and/or mountain biking). The Appalachian National Scenic Trail extends more than 325 miles across the Forest. The Appalachian Trail is located approximately 40 miles west of the Project (the "old" or original Appalachian trail crossed the western shore of the New River near the Byllesby Development, where the New River Trail State Park is now located [McNeely 2017]). In addition, there are 12 National Recreation Trails in the Forest totaling 143 miles (USFS undated a).

Along with National Trails Systems, there are 23 designated Wilderness Areas totaling approximately 140,000 acres within the George Washington and Jefferson National Forest. These designated Wilderness Areas provide primitive types of recreation. There are also 32 special-interest areas in the Forest emphasizing dispersed recreation opportunities (USFS undated a).

Regionally or Nationally Significant Recreation Areas and Recreational Attractions in the Vicinity of the Project

- **Mount Rogers National Recreation Area** (within the George Washington and Jefferson National Forest) - The Mount Rogers National Recreation Area is a United States National Recreation Area located in southwestern Virginia in Grayson County, approximately 15 miles west of the Project. The Mount Rogers National Recreation Area manages National Forest land near Mount Rogers within the George Washington and Jefferson National Forest. Activities in the Mount Rogers National Recreation Area include camping, picnicking, sight-seeing, bird watching, trout fishing, hunting, biking, bicycling, horseback riding, cross-country skiing, and swimming (USFS undated b).

- **Shot Tower Historic State Park** - The Shot Tower Historic State Park is approximately 10 miles downstream of the Project and is managed as part of the New River State Park. The Shot Tower was constructed over 200 years ago to make ammunition for the firearms of early settlers and overlooks the New River. There is a parking lot, interpretive signs providing details of the park and visitors may ascend the tower (VDCR 2017b).

- **Crooked Creek Wildlife Management Area** - The Crooked Creek Wildlife Management Area is located approximately 10 miles southeast of the Project. The 1,796-acre park includes forested and open land and encompasses portions of both Brooked Creek and the East Fork of Crooked Creek. Recreational opportunities include hunting, trapping, primitive camping, trout fishing, hiking, horseback riding, and birding (VDGIF 2017e).

- **New River Trail State Park** - The New River Trail State Park is an approximately 1,668-acre state park located in Carroll, Grayson, Pulaski, and Wythe counties. The park parallels the New River for approximately 39 miles. The New River Trail is a 57-mile linear park that follows an abandoned railroad right-of-way and is primarily used for hiking, biking, and horseback riding. The park's Foster Falls area offers guided horseback trips; canoe and bike rentals; boat launches; gift shops; and a horse arena. Fishing is also a popular activity at New River Trail State Park. Boat ramps are available at Allisonia, Foster Falls, and Austinville.

E.13.1.1.2 Project and Non-Project Recreation Facilities

The Project is accessible by a remote secondary road and is located in a rural setting. The lands on both sides of the Project are steep, but there are some flat parcels along the New River suitable for recreation. The former Norfolk & Western Railroad right-of-way extends along the western shore of the Project and has been converted to the New River Trail State Park, which is typically used for hiking, walking, biking and horseback riding. Most of the land to the west of the Project is owned by the USFS and consists of the George Washington and Jefferson National Forest. Recreation activities at the Project mostly consist of fishing, biking, hiking, and small craft boating.

In association with the previous relicensing effort, Appalachian, the VDWR and the Virginia VDCR entered into a Memorandum of Understanding signed on June 7, 1994 to provide public recreational access to various points along the New River (Appalachian 1994a). As documented in the existing Recreation Plan (Appalachian 1994b) required by Article 411 of the existing license, the Project supports five FERC-approved ("Project") public recreation facilities owned by Appalachian (Table E.13-1, Figure E.13-1). Two of these Project-related recreation facilities are solely operated by Appalachian and the remaining three sites are operated by VDCR or VDWR under the Memorandum of Understanding and Revised Recreation Plan.

Additional ("Non-Project") public recreation facilities or informal access areas exist within the Study Area. Project and Non-Project recreation facilities and access areas within the Study Area that were identified as areas of interest by relicensing participants during the study planning phase of the ILP are also listed and shown on Table E.13-1 and Figure E.13-1.

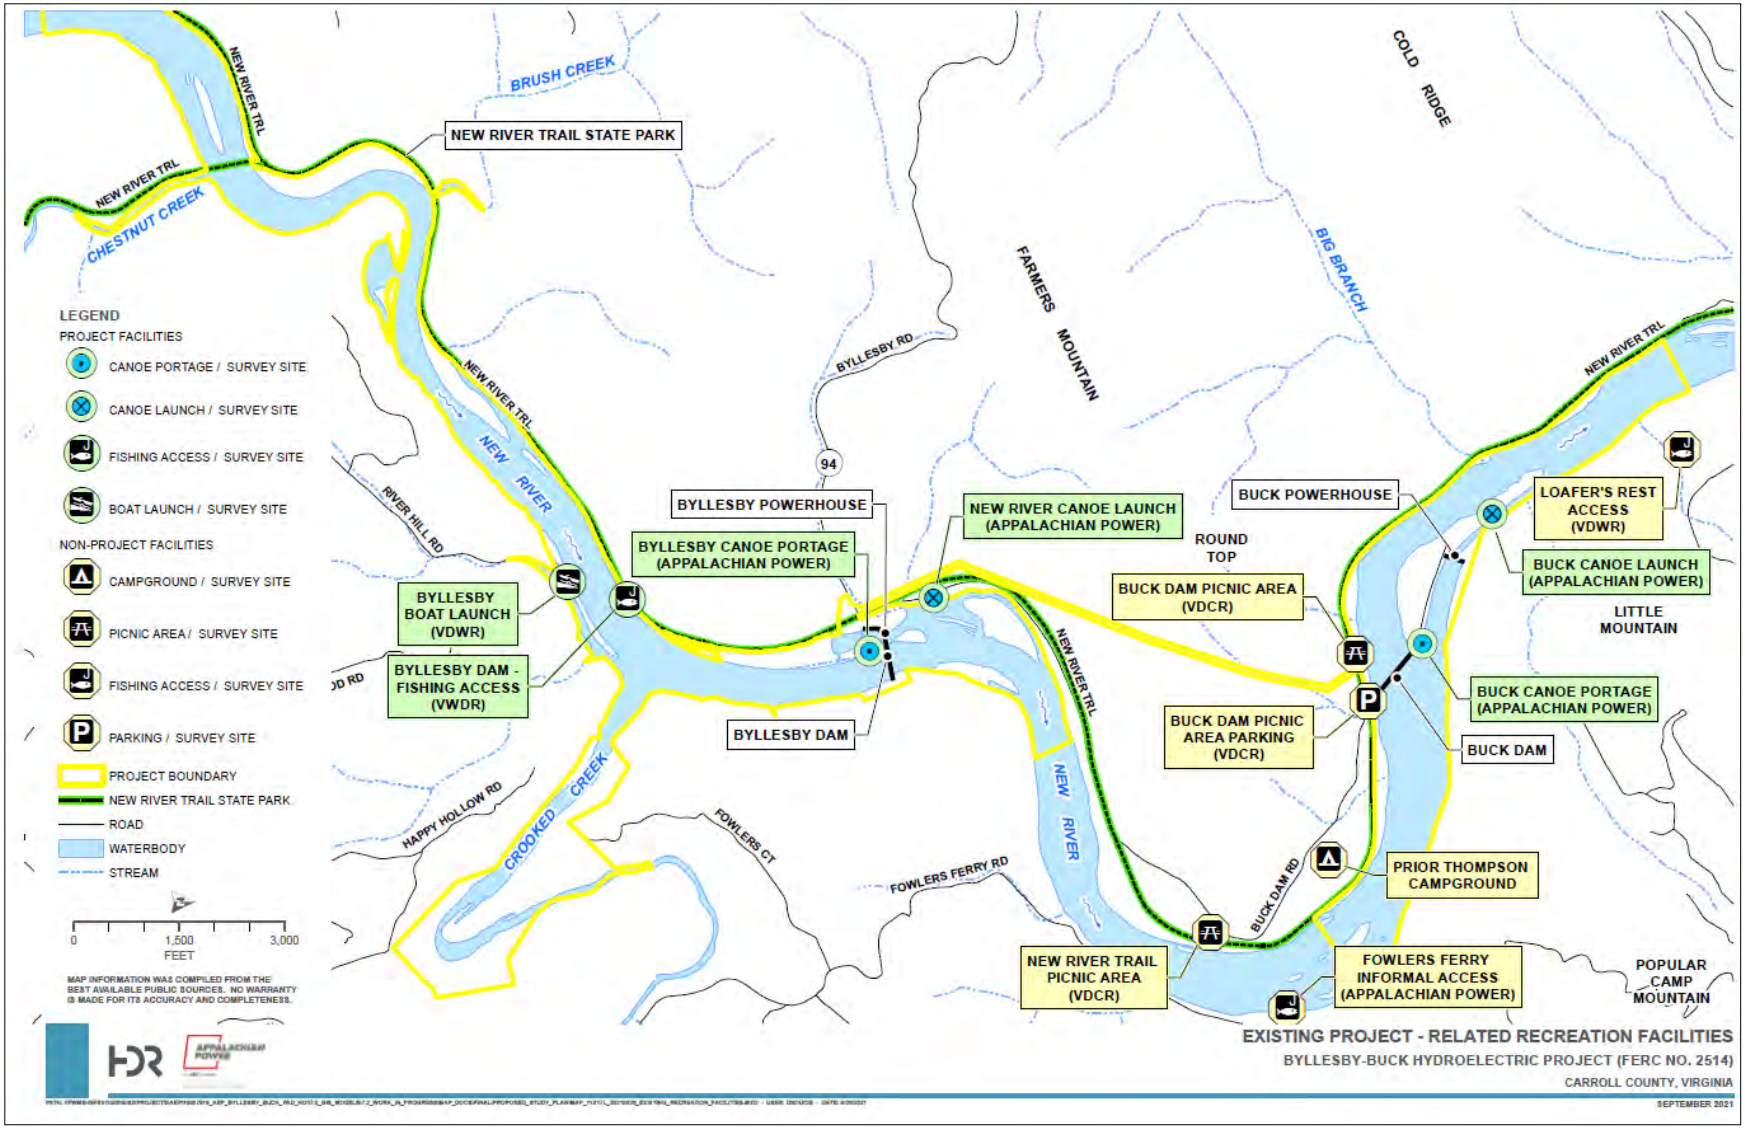

Figure E.13-1. Recreational Facilities Within Recreation Study Area

Table E.13-1.Existing Recreation Facilities at Byllesby-Buck Project

Recreation Facility	Project or Non-Project Facility	Owner/Operator	Amenities	Relationship to Project Boundary
Byllesby Development				
Byllesby VDWR Boat Launch	Project Facility	Leased to and Operated by VDWR	Provides single-lane boat concrete boat launch with gravel parking area.	Within
Byllesby Canoe Portage	Project Facility	Owned and operated by Appalachian	Provides approximate 1,500-foot (ft) portage trail. Site consists of a hand-carry canoe take-out and an information trailhead kiosk for the New River Trail State Park.	Within
New River Canoe Launch	Project Facility	Leased to and Operated by VDCR	Provides small, gravel parking area with short trail leading to a hand-carry boat launch (also serves as put-in for the Byllesby Canoe Portage).	Adjacent to
VWDR Fishing Site	Project Facility	Leased to and Operated by VDWR	Provides a stone embankment cleared for bank fishing and reservoir viewing. Approximately ¾ mile upstream of the Byllesby Dam on the western shore.	Adjacent to
Buck Development				
Buck Dam Canoe Portage	Project Facility	Owned and operated by Appalachian	Provides crushed stone hand-carry take out and a hand-carry put in.	Within
Buck Dam Picnic Area	Non-Project Facility	Owned and operated by VDCR	Provides gravel parking for vehicles, information kiosk, and access to New River Trail. Also provides a picnic area with picnic table, trash can, portable restroom facility, and a hitching post for equestrian trail users.	Adjacent to
New River Trail Picnic Area	Non-Project Facility	Owned and operated by VDCR	Provides upper and lower recreation areas that include benches, picnic tables, bike rack, trash can, grill, and informal angling access to the Buck reservoir.	Adjacent to
Loafers Rest	Non-Project Facility	Leased to and Operated by VDWR	Provides a parking area and walking trail to access the New River. Stakeholders are interested in angler access from the Loafers Rest recreation area to the tailrace of Buck Dam.	Adjacent to
Other				
Fowlers Ferry	Non-Project Facility	Land is owned by Appalachian	No formal recreation activities. Informal activities include picnicking, camping, ATV, fishing, wading, and canoe/kayaking	Outside of

E.13.1.1.3 Aesthetics and Land Use

The Byllesby and Buck developments are located in rural settings along the New River. Neither development is visible from any bridges, roads, or other public transport ways, other than the New River Trail State Park, which runs along the north and west boundaries of the Project, and State Route 737, which parallels the river between Byllesby and Buck. Development along the Project reservoirs and downstream is extremely limited, resulting in river banks dominated by mature tree growth. The river banks and stream bottoms are composed of rock outcroppings that contribute to the rugged theme of the New River in the Project area (Appalachian 1991a).

Appalachian owns minimal land associated with the Project or located within the Project boundary. AEP manages Project lands under its control, including Project facilities, for the purpose of Project operations.

E.13.2 Environmental Analysis

E.13.2.1 Studies in Support of the Current Relicensing

In support of the current relicensing, the Licensee has completed the Recreation Study in accordance with the RSP and the Commission's SPD to support evaluation of the need and potential for enhancement to existing recreation facilities or for additional recreational facilities to support the current and future demand for public recreation in the study area.

The Project and Non-Project recreation facilities and opportunities are being evaluated by Appalachian in accordance with the results of the Recreation Study. The goal of this study was to determine the need for enhancement to existing recreation facilities, or additional recreational facilities, to support the current and future demand for public recreation in the Project area. The objectives of this study were to:

- Gather information on the condition of the six Project-related public recreation facilities and identify any need for improvement;
- Characterize current recreational use of the Study Area;
- Estimate future demand for public recreation at the Project;
- Solicit comments from stakeholders on potential enhancements or new facilities; and
- Analyze effects of continued Project operation on Project-related recreation facilities.

In support of the Recreation Study, Appalachian and their consultants implemented a range of data collection techniques, including a Recreation Facility Inventory and Condition Assessment, a virtual

meeting and in-person site visit with stakeholders, a recreation visitor use online survey, and trail camera installations. Data gathered from these methods collectively illustrate general trends of the Project, which are described in detail in the Recreation Study Report filed with the ISR and summarized below.

E.13.2.1.1 Recreation Facility Inventory and Condition Assessment

Appalachian's sub-consultant (LPDA) conducted a Recreation Facility Inventory and Condition Assessment of seven sites, five of which are FERC-approved Project facilities. LPDA recorded the following information for each recreational facility including:

- A description of the type and location of existing recreation facilities;
- The type of recreation provided (boat access, angler access, picnicking, etc.);
- Length and footing materials of any trails;
- Existing facilities, signage, and sanitation;
- The type of vehicular access and parking (if any);
- Suitability of facilities to provide recreational opportunities and access for persons with disabilities (i.e., compliance with current Americans with Disabilities Act (ADA) standards for accessible design); and
- Photographic documentation of recreation facilities and GPS location.

Additionally, a qualitative assessment of the condition of the recreation facilities was performed using a Facility Inventory and Condition Assessment Form.

LPDA observed several common themes among the recreation facilities including lack of ADA accessibility, aging though functional furnishings, informally developed amenities, incomplete signage, and deferred maintenance. LPDA noted that the Project is set in scenic, natural surroundings and the historic dams provide cultural interest. LPDA noted there is a high potential for increasing recreation value of the sites, both by improving the existing conditions and by developing related amenities.

E.13.2.1.2 Site Visit with Stakeholders to Discuss Existing and Future Recreational Opportunities

Appalachian convened a site visit with key relicensing stakeholders to discuss existing and future recreational opportunities at the Project on October 28, 2020. Prior to the site visit, Appalachian held a virtual meeting on October 21, 2020 with involved stakeholders to share preliminary results of the Recreation Study.

E.13.2.1.3 Recreation Visitor Use Online Survey

HDR developed an online survey drawing from general concepts and guidance from the National Visitor Use Monitoring Handbook (USFS 2007) as well as from other FERC-approved relicensing studies for recreation visitor use surveys. The online survey was administered through the Project's relicensing website and offered respondents the opportunity to provide survey responses electronically from April through November 2020.

The online questionnaire was designed to collect information about:

- General user information;
- Resident/visitor;
- Purpose and duration of visit;
- Distance traveled;
- Day use/overnight lodging;
- History of visiting the site or area;
- Types of recreational activities respondents participated in during their visit, including primary and secondary recreation activities;
- Other recreational sites that respondents visited during their trip;
- General satisfaction with recreational opportunities, facilities, and the respondents overall visit and/or areas that need improvement;
- Effects of Project operations on recreation use and access; and
- Accessibility of facilities.

A high-level summary of all the recreation facility user responses is provided below:

- Eighty-four percent of the responses came from four recreation facilities: Byllesby Boat Launch (VDWR), Buck Dam Canoe Portage, New River Canoe Launch, and New River Trail Picnic Area, indicating these sites were the most frequently utilized by online survey participants.

- Forty-two percent of the survey respondents traveled from three nearby zip code areas, with 92 percent considering themselves to be regular visitors to the recreation facility (considered at least 3 or more times a year) and staying at the Project an average length of 5 hours per trip. Eighty-three percent of respondents did not stay overnight at the Project.

- Males made up 74 percent of the respondents, 49 percent were in their thirties and forties.

- Facility usage followed traditional seasonal recreation patterns with May, June, and July being the peak months.

- Fishing and canoe/kayaking were the most popular activities at the Project documented in the online survey.

- Visitors rated recreational facilities on the following metrics: accessibility, parking, crowding, safety, condition, availability, and overall experience. The sliding scale rating system indicated that visitors generally found the individual metrics and general overall experience "acceptable". The only metric that was not rated highest in the acceptable category was the available facilities, which was rated neutral.

E.13.2.1.4 Recreational Use Documentation

Appalachian documented usage of the recreational areas of interest through the installation of trail cameras. Eight trail cameras were installed on October 15 and 16, 2019 and were removed on November 5, 2020. During the trail camera component of the study, HDR downloaded data from the cameras on eight different occasions, capturing thousands of photos.

Review of the trail camera data indicates that the Project is well-used during the spring to fall months, which is attributed largely to the easy access along the entire left bank via the New River Trail. While some of the recreation facilities were used for their intended use, some were used differently than predicted, as further discussed below. Additionally, it was concluded that parking areas at the Project are sufficiently large enough to meet the current demand during a typical and peak recreation day.

Project Facilities Trail Camera Assessment

The Project facilities most frequented by users are the Byllesby VDWR Boat Launch and the parking area near the Byllesby Canoe Portage. These two Project facilities provide a range of recreation opportunities including boating, canoeing, fishing, walking, biking, and hiking. The Byllesby VWDR Boat Launch has the easiest boat access to the New River within the Project Boundary. Fishing is also popular along the shoreline at this facility.

The Byllesby Canoe Portage parking area was largely used to access the New River Trail (including biking, hiking, and walking and dog walking) rather than the expected use for loading and unloading kayaks and canoes. The New River Canoe Launch was used as intended (canoe/kayak put-in), but more frequently used for bank fishing or relaxing along the sandy shore. This facility was not as popular as the Byllesby VDWR Boat Launch and the Byllesby Canoe Portage but generally had a consistent amount of foot traffic, especially during the warmer days.

Finally, Buck Dam Canoe Put-In was assessed by the trail camera and found to be seldomly used but when it was, it was used as a put-in or for bank fishing. Stakeholders noted during the October 28,

2020 site visit that users cross the Buck bypass to Mountain Island[14] to gain angler access further downstream. It is possible that use around this area is higher than observed on the trail cameras, but the Buck Dam Canoe Put-In itself was generally not used as captured by the trail camera. On approximately three occasions, the camera captured motorboats accessing the tailrace to fish.

Non-Project Facilities Trail Camera Assessment

Just upstream of the Buck Dam Canoe Put-In, HDR used a time lapse camera to record activity on the right bank of the tailrace. This area is referred to for purposes of this study as Buck Dam – Fishing Access which is accessed from the VDWR's Loafers Rest Non-Project facility. The general area of the Buck Dam – Fishing Access was understood by Appalachian to be of interest to the stakeholders as a fishing spot during the development of the RSP; however the camera in this area recorded approximately two users during the entire survey window. At the October 28, 2020 site visit with the stakeholders, the VDWR noted that there is a No Trespassing sign (public access is prohibited proximate to the powerhouses and dams due to public safety and security concerns) and users are aware of this and avoid the area. Prior to the installation of the No Trespassing sign, this site was suggested to be popular for angler access.

The New River Trail Picnic Area is a Non-Project facility maintained and operated by the VDCR. The upper and lower access provides a wide range of recreational opportunities including picnicking, horseback riding, biking, walking (and dog walking), relaxing, grilling, fishing, observing wildlife and more. This area is accessed directly from the New River Trail and recorded consistent usage throughout the survey window, especially from spring to fall.

The final Non-Project recreation facility assessed with the trail cameras was the Buck Dam Picnic Area. This facility is just downstream of the New River Trail Picnic Area and is also on the New River Trail, therefore, the use was very similar and generally included picnicking, hiking, biking, horseback riding and walking (and dog-walking). This area has direct access from the New River Trail and saw consistent usage throughout the survey window especially from spring to fall.

[14] The Buck Dam Canoe Put-In is located on Mountain Island which is an island between the Buck powerhouse and the bypass ().

E.13.2.1.5 Additional Study Consultation Regarding Potential Recreation Facilities Enhancements

Since the filing of the ISR, Appalachian conducted additional consultation with VDWR to evaluate potential Project and Non-Project recreation facility improvements to be included as part of Appalachian's licensing proposal, as follows:

- Site visit to the VDWR Loafer's Rest recreation facility with VDWR, Appalachian, and Appalachian's consultants on March 24, 2021.
- Conference call) with VDWR, Appalachian, and Appalachian's consultants for the Recreation Study on June 29, 2021 to discuss priorities for potential Project and Non-Project recreation facility improvements and to introduce preliminary concepts for development of the VDWR Loafer's Rest recreation facility.

E.13.2.2 Project Impacts on Recreation and Aesthetics

In SD3, FERC identified the following environmental issues to be addressed in FERC's NEPA document:

- Effects of continued project operation and maintenance on recreation, land use, and aesthetics within the project area.
- Adequacy of existing recreational facilities and public access to the Project (such as fishing in the tailraces) to meet current and future recreational demand.

Overall, the powerhouses at both developments, as well as the primary spillways, have retained the same look since construction was completed in 1912. The powerhouses are both of brick construction with tall, slightly recessed window bays and simple corbelled cornices. The overall appearance is typical of industrial architecture of the time. Facilities related to both developments are well maintained, as are the surrounding grounds. The overall effect is an aesthetically pleasant visual experience for an industrial-oriented facility (Appalachian 1991a).

The Recreation Study captured consistent recreation usage at most of the Project and Non-Project facilities, with usage peaking on the weekends, holidays, and warmer months, as anticipated. In general, the recreation facilities experienced similar types of recreational activities and consistent recreational usage over the study period, especially from May through October. The results of the Recreation Study, as summarized in the sections above, indicate the following:

- Existing Project and Non-Project facilities are well-used but sufficiently sized to meet current and expected future demand. Based on the capacity assessed through the trail camera assessment for the Recreation Study, the parking areas at the Project are sufficient to meet the current demand during a typical and peak recreation day.

- The New River Trail provides a unique opportunity to access most of the recreation facilities in otherwise remote locations.
- Due to the age of existing facilities, there are opportunities for enhancements and improvements or general maintenance across the facilities. Based on feedback from recreational visitors to the Project area through the online survey, there is strong local interest in maintaining and improving the recreation facilities at the Project for the local economy.
- Numerous comments and recommendations were made by Recreation Study participants for improved signage regarding intended use, restricted access areas (e.g. tailrace areas, dams), safety, and consistent FERC, regulatory, and identification signage.
- The trail camera and online survey results indicated that fishing (and fishing via boating) and canoe/kayaking were the primary recreation activities at Project and Non-Project facilities.
- The existing ownership and maintenance responsibilities for Project and Non-Project facilities within, adjacent to, or near the Project Boundary (i.e., Appalachian, VDWR, VDCR, and USFS) appears to be appropriate and conducive to meeting recreational needs and demands, with the exception of the former USFS campground area. The Thompson Campground located between Byllesby and Buck Dams was frequently mentioned in the Recreation Study online survey comments frequently. The VDCR explained during the recreation site visit conducted by Appalachian in the fall of 2020 that previous efforts (1990s and as recently as two years ago with an attempt to reach terms of a 99-year lease) by the VDCR to acquire the land from USFS were unsuccessful. This area is the most suitable area for a campground near the Project and has existing picnic areas, horse facilities, and general campground infrastructure. This area remains of interest to the VDCR and online survey users. While Appalachian is generally supportive of VDCR's interests in obtaining rights to this area, the campground is located entirely outside of the Project boundary and not on lands owned or controlled by Appalachian.
- The portages at each development are relatively long and not widely used, but they serve their intended purposes for boaters looking for an opportunity to paddle this continuous stretch of the New River, inclusive of slower moving impoundment area. The Byllesby portage takeout cannot be feasibly relocated due to the extensive wetland area that extends along the left bank (as viewed downstream) upstream of Byllesby Dam. The Byllesby portage put-in (i.e., New River Canoe Launch) is adequate and widely used for access to the Byllesby impoundment. Similarly, the Buck portage put-in is likely more often used for tailrace or bypass reach fishing access than for launching canoes or kayaks. The put-in is difficult, and there are opportunities to reorient and design the put-in for easier launch.
- VDWR and VDCR are interested in gaining additional points of river access for emergency operations.
- There is general interest by recreational visitors and VDWR for improved facilities for fishing and river-based recreation downstream of Buck Dam, including the informal area known as Loafer's Rest.

The Licensee does not anticipate that operation and maintenance of the Project over the new license term will have any short- or long-term, unavoidable, adverse impacts on recreational resources, land use, or aesthetics.

E.13.3 Protection, Mitigation, and Enhancement Measures Proposed by the Applicant, Resource Agencies, and/or Other Consulting Parties

Appalachian is presently developing an updated draft Recreation Management Plan which will provides documentation of the existing Project facilities, agreements with agencies for operation and maintenance of facilities within the Project Boundary (if and as applicable), and proposed enhancement measures for the new license term. Enhancements are anticipated to include improvements to signage throughout the Project Boundary, upgrades to the VDWR Byllesby Boat Launch and improvements to the Buck portage put-in. Appalachian is also proposing to construct new facilities at VDWR's Loafer's Rest area, to be maintained by VDWR in accordance with the lease from Appalachian for this land.

Appalachian expects to distribute the draft Recreation Management Plan to VDWR, VDCR, and other relicensing study participants for comments in conjunction with the USR so that a draft Recreation Management Plan can be filed with the FLA.

E.14 Historic and Archaeological Resources

E.14.1 Affected Environment

In considering a new license for the Project, FERC has the lead responsibility for compliance with applicable federal laws, regulations, and policies pertaining to historic properties, including the NHPA, as amended.[15] Section 106 of the NHPA (Section 106)[16] requires federal agencies to take into account the effects of their undertakings on historic properties and to afford the Advisory Council on Historic Preservation a reasonable opportunity to comment.

The Section 106 process (defined at 36 CFR Part 800) is intended to accommodate historic preservation concerns with the needs of federal undertakings through a process of consultation with agency officials, the State Historic Preservation Officer (SHPO), federally recognized Indian Tribes, and other parties with a potential interest in an undertaking's effects on historic properties. The goals of the Section 106 process are to:

- Identify historic properties that may be affected (directly and/or indirectly) by an undertaking;
- Assess the effects of an undertaking on historic properties; and
- Seek ways to avoid, minimize, or mitigate adverse effects on historic properties through consultation.

Historic properties are defined in 36 CFR Part 800 as any pre-contact or historic period district, site, building, structure, or individual object listed in or eligible for inclusion in the NRHP. This term includes artifacts, records, and remains that are related to and located within historic properties, as well as properties of traditional religious and cultural importance (often referred to as "traditional cultural properties") that meet the NRHP criteria.

The Secretary of the Interior has established the criteria for evaluating properties for inclusion in the National Register (36 CFR Part 60). In accordance with the criteria, properties are eligible if they are significant in American history, architecture, archaeology, engineering, or culture. The quality of significance present in historic properties that possess integrity of location, design, setting, materials, workmanship, feeling, and association, and:

- Are associated with events that have made a significant contribution to the broad patterns of our history; or
- Are associated with the lives of persons significant in our history; or

[15] 54 USC §300101 et seq.
[16] 54 USC §306108

- Embody the distinctive characteristics of a type, period, or method of construction, or that represent the work of a master, or that possess high artistic values, or that represent a significant or distinguishable entity whose components may lack individual distinction; or
- Have yielded or may be likely to yield information important in prehistory or history.

E.14.1.1 Area of Potential Effects

An area of potential effect (APE) is defined as the geographic area or areas within which an undertaking may directly or indirectly cause alterations in the character or use of historic properties, if any such properties exist. The APE is influenced by the scale and nature of an undertaking and may be different for different kinds of effects caused by the undertaking. The Commission has not yet defined an APE for the Project. In the context of the relicensing process, FERC generally defines the APE as follows: "The APE includes all lands within the Project Boundary. The APE also includes any lands outside the Project Boundary where cultural resources may be affected by Project-related activities that are conducted in accordance with the FERC license."

Because the Project Boundary encompasses all lands that are necessary for Project purposes, all Project-related operations, potential enhancement measures, and routine maintenance activities associated with the implementation of a license issued by the Commission are expected to take place within the Project Boundary. The proposed APE is consistent with the potential scope of Project effects and the manner in which the Commission has defined the APEs for similar hydroelectric relicensing projects in the region.

E.14.1.2 Existing Discovery Measures

Articles 409 and 410 of the existing license for the Project includes measures to protect and manage historic properties:

> Article 409. The licensee shall consult with the Virginia SHPO and develop and implement a cultural resources management plan to avoid and mitigate any impacts to the historical integrity of the project dams, spillways, and powerhouses, and the Byllesby caretaker's house and transformer house, from routine maintenance and repair work conducted during project operation.
>
> Article 410. If archeological or historic sites are discovered during project operation, the licensee shall: (1) consult with the Virginia SHPO; (2) prepare a cultural resources management plan and a schedule to evaluate the significance of the sites and to avoid or mitigate any impacts to any sites found eligible for inclusion in the National Register of Historic Places; (3) base the plan on the recommendations of the SHPO and the Secretary of the Interior's Standards and Guidelines for Archeology and Historic Preservation; (4) file the plan

for Commission approval, together with the written comments of the SHPO on the plan; and (5) take the necessary steps to protect the discovered sites from further impact until notified by the Commission that all of these requirements have been satisfied. The Commission may require cultural resources survey and changes to the cultural resources management plan based on the filings. The licensee shall not implement a cultural resources management plan or begin any land-clearing or land-disturbing activities in the vicinity of any discovered sites until informed by the Commission that the requirements of this article have been fulfilled.

Under Article 409 of the current license, in 1996, Appalachian filed for FERC approval a Cultural Resource Management Plan to avoid effects that may result from maintenance or repair work at the Byllesby-Buck Project (Appalachian 2019a).

E.14.1.3 Identification of Archaeological and Historic Resources

E.14.1.3.1 Previous Cultural Resources Studies

A Phase 1A Archaeological Investigation was conducted by Appalachian for the previous relicensing (Louis Berger & Associates, Inc. 1991). As summarized in the Phase 1A report, only one archaeological site, approximately 0.75 miles downstream of the Buck powerhouse on the east bank of the New River, has been previously recorded in the vicinity of the Project. Additional sites have been recorded within lands managed by the USFS and in the vicinity of the Project.

At the Byllesby development, the potential for prehistoric archaeological sites is limited due to past disturbances, including Project construction. At the Buck Development, the potential for prehistoric archaeological sites is also limited, particularly in the area adjacent to the powerhouse which has been previously disturbed by construction and maintenance activities. With respect to “Mountain Island” (in the middle of the channel, starting at and extending downstream of the Buck dam), the potential for intact cultural deposits on the eastern end of Mountain Island is low due to dam construction and past disturbances, though the remaining portion of Mountain Island was determined to be moderate due to its undisturbed nature and higher elevation areas that may have offered prehistoric populations well-drained areas for occupation.

In support of developing the 1991 license application and other relicensing efforts, a comprehensive cultural resource evaluation of 19 hydroelectric power generating facilities of Virginia was conducted by Louis Berger & Associates, Inc. for Appalachian (Louis Berger & Associates 1991). Based on this assessment and investigations performed for the previous relicensing, the Byllesby-Buck (New River) spillways, dams, and powerhouses have been determined to meet National Register Criteria for Evaluation as set forth in 36 CFR §60.4, a finding with which the Virginia SHPO and FERC have previously concurred.

E.14.2 Environmental Analysis

E.14.2.1 Studies in Support of Current Project Relicensing

Concurrent with the January 7, 2019 PAD and NOI required by the ILP, Appalachian requested designation as the Commission non-federal representative for carrying out informal consultation pursuant to Section 106. The Commission granted Appalachian's request by notice dated March 8, 2019. Pursuant to 36 CFR §800.4(a)(1), in a letter dated September 1, 2020, Appalachian consulted with the Advisory Council on Historic Preservation, the U.S. National Park Service, Bureau of Indian Affairs, Virginia Department of Historic Resources/State Historic Preservation Office (VDHR/SHPO), the Cherokee Nation, the Catawba Indian Nation, the Delaware Nation, the Pamunkey Indian Tribe, the Eastern Band of Cherokee Indians, and the Archaeological Society of Virginia, requesting concurrence on determining the APE for the Project defined as all lands necessary for Project operations.

In August 2020, Appalachian's sub-consultant [Terracon Consultants, Inc. (Terracon)] reviewed the Virginia Cultural Resource Information System (V-CRIS) to identify previously recorded cultural resources within a 0.5-mile radius of the Study Area. On September 10, 2020, Terracon staff traveled to the VDHR office in Richmond, VA to gather additional information otherwise unavailable in V-CRIS.

Detailed study results are included in the Cultural Resources Study Report in Volume V of this DLA, which is filed as CUII \\ Privileged. The Cultural Resources Study Report was transmitted on September 13, 2021 to the SHPO and consulting Tribes for their review and concurrence with the report's recommendations.

E.14.2.1.1 Archaeological and Geomorphological Survey

Background research performed by Terracon indicated three previously recorded archaeological sites are within the Project boundary: 44CA3, 44CA33, and 44CA121. Sites 44CA3 and 44CA121 are U.S. Army Corps of Engineers sluices that were cut into the shoals of the New River in late nineteenth century. Site 44CA33 was recorded as being a prehistoric open-air site but was never professionally investigated. The National Register of Historic Places (NRHP) eligibility of these three sites had not been assessed.

From October 19 to 22, 2020, Terracon conducted an archaeological assessment of portions of the Project APE. Areas south of Byllesby were accessed by boat, while areas north of Byllesby were accessed by land where possible. The riverbank and islands between Byllesby and Buck were generally not observed due to accessibility and safety concerns with rapidly flowing water and shoals. Terracon attempted to re-locate archaeological sites, although neither was observed during the field

work, possibly due to high water levels. Archaeological and geomorphological investigations of the Project found that most of the APE is either steeply sloped or deeply buried in historic alluvium. In addition, there was very little erosion or other Project related effects in any portions of the APE.

Nine different portions of the Project area considered to have the highest potential for containing archaeological resources were examined using shovel testing. In addition, Terracon tried to relocate the three previously recorded sites, 44CA3, 44CA33, and 44CA121 (Figures 1 and 2; Table 1). As a result of the survey, only site 44CA33 was identified. This temporally non-diagnostic lithic scatter is recommended as being ineligible for inclusion in the NRHP. Sites 44CA3 and 44CA121 could not be relocated, possibly because the water level was too high. In addition to the archaeological investigations, geomorphological investigations were conducted by Seramur & Associates from October 26–28, 2020, and again on April 20, 2021. Twenty hand auger borings were placed in the same nine areas where archaeological investigations took place. Based on the geomorphological analysis, only the area near site 44CA33 had the potential to contain buried archaeological deposits. Currently, this area is not being affected by Project operations, including erosion. The other eight areas did not have suitable landforms for containing undisturbed archaeological resources.

E.14.2.1.2 Architectural Survey

In addition to the archaeological sites listed above, there are three aboveground resources identified within the Project boundary—the Buck Hydroelectric Facility (017-0022); the Byllesby Dam (017-5154); and the Norfolk and Western Railway Cripple Creek Extension (077-5068). The Byllesby and Buck facilities were determined to be eligible for the NRHP (Berger 1990), as was the Norfolk and Western Railway. None of these historic resources are currently being affected by Project operations. The three above-ground historic resources are eligible for inclusion in the National Register of Historic NRHP and were revisited during the field work. All three remain eligible for listing in the NRHP.

E.14.2.2 Project Impacts on Historic and Archaeological Resources

In SD3, FERC staff identified the following environmental issues to be addressed in their NEPA document:

- Effects of project operation and maintenance on historic properties and archeological resources that are included in, eligible for listing in, or potentially eligible for inclusion in the National Register of Historic Places.
- Effects of project operation and maintenance on any previously unidentified historic or archeological resources or traditional cultural properties that may be eligible for inclusion in the National Register of Historic Places.

Based on the initial background research and site investigations, and the fact that none of the properties eligible for listing in the NRHP are being impacted, Terracon concluded that no historic properties are currently being affected by continued Project operations. However, Terracon recommended if new construction or significant ground disturbance occurs in areas that have the potential to contain archaeological resources (including areas with an unknown potential), additional archaeological investigations may be warranted and consultation with the SHPO would be necessary. Similarly, if there are any substantial changes to either the Byllesby or Buck facilities, consultation with the SHPO and other consulting parties would be required.

A summary listing of Cultural Resources within the APE is provided in the table below.

Table E.14-1.Cultural Resources within the APE

Resource ID	Description	NRHP Eligibility	Management Recommendation
44CA3	Late 19th century sluice	Not Relocated	No Effect
44CA33	Prehistoric lithic scatter	Not Eligible	None
44CA121	Late 19th century sluice	Not Relocated	No Effect
017-0022	Buck Hydroelectric Facility	Eligible	No Effect
017-5154	Byllesby Hydroelectric Facility	Eligible	No Effect
077-5068	Norfolk and Western Railway Cripple Creek Extension	Eligible	No Effect

Although no significant archaeological resources are being affected by the Project, the investigations performed for this relicensing did identify one area within the APE that has the potential for containing intact archaeological sites. This approximately 47.5-acre area includes a terrace located on the east bank of the river at the north end of the Project where archaeological site 44CA33 was found. Based on the archaeological and geomorphological studies, this is the only area within the Project that has the potential to contain intact archaeological resources. Although the area is not currently being affected by the Project, nor will continued operations of the Project affect the area through erosion or other mechanisms, Terracon recommended that a Phase I intensive archaeological survey take place if any ground disturbing activities were to occur in this area.

Appalachian is not currently proposing modifications to Project operations or Project-related land-clearing or land-disturbing development activities within the APE that would result in an impact to any historic properties. The continued operation of the Project as proposed by Appalachian and subject to the continued protections of an updated cultural resources management plan as described below is not expected to have any unavoidable adverse effects on historic or archaeological resources.

E.14.3 Protection, Mitigation, and Enhancement Measures Proposed by the Applicant, Resource Agencies, and/or Other Consulting Parties

Appalachian is presently updating the existing Cultural Resources Management Plan in accordance with the *Guidelines for the Development of Historic Properties Management Plans for FERC Hydroelectric Projects* promulgated by FERC and the ACHP on May 20, 2002 and to include the results and recommendations contained in the Cultural Resources Study Report.

The HPMP for the Project will describe appropriate management measures to avoid, minimize, or mitigate adverse effects on existing and yet-to-be-identified historic and archaeological resources, including any unanticipated discoveries of archaeological material or human remains, over the term of the new license issued for the Project. The measures provided in the HPMP will direct the Licensee's management of NRHP-eligible historic properties within the Project's APE.

Appalachian will develop the HPMP in consultation with the Consulting Parties. Through this consultation, Appalachian will develop management measures to be incorporated into the HPMP. Appalachian has outlined the following two goals for managing historic properties within the Project's APE:

- Support continued normal operation of the Project while maintaining and preserving the integrity of historic properties; and
- To the fullest extent possible, avoid, minimize, or mitigate adverse effects on historic properties within the APE.

Subject to completion of required consultation, a draft HPMP may be filed with the FLA.

E.15 Economic Analysis

This section will be updated to reflect licensing proposals, including recommended and proposed PM&E measures, in the FLA. This section will also include an implementation or construction schedule for any proposed measures or facilities, showing the intervals following issuance of a license when implementation of the measures or construction of the facilities would be commenced and completed, and an estimate of the costs of construction, operation, and maintenance, of any proposed facilities, and of implementation of any proposed environmental measures.

E.16 Consistency with Comprehensive Plans

Section 10(a)(2) of the Federal Power Act (16 USC §803(a)(2)(A) requires the Commission to consider the extent to which a project is consistent with federal and state comprehensive plans for improving, developing, or conserving a waterway or waterways affected by a project. Under 18 CFR

§5.18(b)(5)(ii)(F) each license application must identify relevant comprehensive plans and explain how and why the proposed project would, would not, or should not comply with such plans. In addition, the license application must include a description of any relevant resource agency or Indian tribe determination regarding the consistency of the project with any such comprehensive plan.

Comprehensive plans determined to be potentially relevant to the Byllesby-Buck Project and reviewed for consistency with this license application are presented in Exhibit H of this DLA.

E.17 Consultation Documentation

Through the pre-filing consultation stage of the ILP, Appalachian consulted with Federal, state, interstate and local resource agencies, Indian tribes, non-governmental organizations, and unaffiliated members of the public. A summary and copies of formal consultation correspondence is provided in Appendix A.
